Chronic complications.—Intracranial abscess was often not suspected, in spite of a history of aural infection, until general symptoms of raised pressure or gross focal signs were present; and even then hospital records showed that a wrong diagnosis was often made. The history was of the utmost importance in giving a clue to the nature of the lesion. Examination of the cerebro-spinal fluid should be made, for increased protein and cell count provided valuable information. Dr. Riddoch related a typical case of the condition, headache being a very prominent symptom. Another group characterised by recurrent headaches, although usually with the absence of other features, suggesting the formation of a chronic brain abscess, was chronic arachnoiditis. Sometimes, however, alarming symptoms such as papillœdema might arise. In one such case related by H. Cairns the papillœdema was followed by optic atrophy, succeeded by blindness, the child remaining otherwise healthy.

DISCUSSION.

The PRESIDENT agreed that tenderness over the mastoid or a limited mastoiditis was not a necessary indication that the mastoid was involved; he hoped it would not be included in the indications for operation. He also agreed that a substitute was needed for the term "serous" meningitis.

Sir JAMES DUNDAS-GRANT, referring to the diagnosis of lateral sinus thrombosis, said it usually was easy to get fluctuation between the internal jugular vein not exposed and the exposed sinus, and if that was absent the observer could be sure a complete blockage existed below. Extradural abscess could exist without any symptoms of it being present. With reference to mastoid tenderness in mastoiditis, otologists had laid it down that tenderness over the mastoid in the first week of acute suppurative inflammation in the ear indicated merely a congestion. But if it persisted longer something more was probably developing in the superficial cells. He had seen one or two cases of disease in the ponto-cerebellar angle in which the cerebellar symptoms were well marked, but disappeared when the dura mate was laid open and a puncture made in the meninges allowing of the escape of fluid. In cerebello-pontin angle conditions the labyrinthine reactions shoul be done.

Dr. C. P. SYMONDS admitted the difficulty o deciding whether, in a given case, a cerebral absces was or was not present. When it was reasonabl certain that one was present, its localisation o neurological grounds was not particularly difficul When a case was dealt with in which abscess wa proved, it was valuable to review the history of th case and see what were the points which first led t the suspicion that such invasion had occurred. H would like otologists to decide at what point in case of otitis media the headache, pain, fever, &c must be regarded as indicating more than the usu ear condition—i.e., as justifying the suspicion of a intracranial complication; also, what was the norma clinical picture of post-operative convalescenc from acute otitis media or mastoidectomy. H described a clinical picture which at first seemed t resemble that of cerebral abscess, but which h considered to be due to a localised basal meningit with secondary internal hydrocephalus. He had ha three such cases, and in each the story was much th same: an acute otitis media or exacerbation of a old otitis media, followed by symptoms indicatin meningitis. Exploration showed the dura mater t be under great tension. There were no localisin signs of cerebellar or temporal abscess in his three case and each of them made a complete recovery. H related one of them in detail.

Mr. J. S. FRASER said he was interested to he Dr. Riddoch mention the time-honoured text-boo dictum concerning tenderness along the intern jugular vein. In his own experiences this was n a symptom of lateral sinus thrombosis. He ha found that mastoiditis alone seldom or never cause a temperature of over 100° F., except in the case young children, and in adults suffering from influen or other febrile conditions. The ordinary case mastoiditis did not complain of headache aft the operation; and should severe headache occ at such a time he suspected an intracranial complic tion, probably meningitis.

Mr. F. W. WATKYN-THOMAS said he did not see ho mastoiditis alone could cause headache at the verte unless there was some dural involvement. But th possibility of accessory sinus infection should always b borne in mind. In disease conditions at the cerebell pontine angle he had several times noted that th patient had the head firmly tucked over to th affected side, when there was no question of stern mastoid involvement, and every effort to straighte it was resented.

Mr. T. B. LAYTON considered that after an acu mastoid all the untoward symptoms should be go in 48 hours, and the pain should have ceased. If no washing out the wound with a pint of saline shou cause the temperature to come straight down. this did not happen he would suspect some furth complication. He did not think that tenderne over the mastoid was a symptom of inflammation the cancellous bone, which was what one wanted recognise; it was an indication that inflammati had spread through the cortical bone and was begi ning to involve its periosteum. In acute otitis med pain disappeared so soon as the drum-head w ruptured or paracentesis had been performed, it did so after the patient had had a good slee If, however, pain should appear there next day would begin to suspect that the bone behind t

middle ear was involved. A thrombosed sinus should be left alone after dealing with the inflamed area around.

Mr. LOWNDES YATES said that sometimes he had been assisted by examining the type of mastoid which the operation revealed. In many cases the mastoid had thinned, and in those there was apt to be tenderness during the inflammation of the mastoid cells, due to the periostitis overlaying it. When the bone was very thick he had noted a liability to intracranial complications.

Mr. SYDNEY SCOTT spoke of the cases in which a brain abscess was so large that it involved the whole temporo-sphenoidal lobe and extended into the occipital lobe, and was undiagnosable by the physician or the neurologist. He had seen such a case without optic neuritis, and when the dura mater was exposed there was no increase in the intracranial pressure. In one patient he saw a brain tumour had been diagnosed for two years, but she was found to have in abscess in the region of the uncinate gyrus; it was an abscess of a solid type. No patient should be allowed to go to the post-mortem room with unrecognised empyema.

Mr. H. V. FORSTER referred to the value of exploration in the recognition of brain abscess, and mentioned five cases in which this enabled him to arrive at the diagnosis, and the patients got well.

Dr. RIDDOCH briefly replied.

Dr. A. B. ROSHER read a paper on the examination of the cerebro-spinal fluid as an aid to the diagnosis of otological conditions. Discussion followed and a number of cases were shown.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

Maternal Mortality Report.

A MEETING of this Section was held on Nov. 21st, with Sir EWEN MACLEAN, the President, in the chair, when a discussion was held on the interim report of the Departmental Committee on Maternal Mortality and Morbidity. The discussion was opened by Dr. T. WATTS EDEN and Dr. J. S. FAIRBAIRN.

Dr. Eden described the general scheme of the report and welcomed the Committee's endeavours to ascertain the "primary avoidable factor" in each of the 2000 deaths which were investigated. This factor was not necessarily, he said, the direct cause of death, as in some instances the factor was failure to carry out any antenatal supervision. Some interesting facts came out of the inquiry, one being the number of deaths which occurred during normal labour. The occurrence of sepsis in so-called normal labour was very high indeed, and in the majority of these cases no primary avoidable factor could be discovered. In explaining these two crucial subjects—viz., the cause of death in normal labour, and the frequency with which sepsis follows normal labour—the Report gave no help at all. The Committee's recommendations as to the provision of better treatment for cases of miscarriage in hospitals were to be commended. Dr. Eden discussed the training of medical students, and said that the schemes put forward by the Committee should have the utmost consideration. The increased number of obstetrical cases suggested by the Committee for the training of students could only be obtained if the Government and the local authorities were willing to place at the disposal of teachers very much increased facilities for the training of both students and post-graduates in connexion with the new hospitals which had recently come under the control of local authorities. Such an opportunity might never arise again, and it ought to be made use of to the utmost.

Dr. Fairbairn was impressed with the unanimity of the members of the Committee. He referred to other reports where the maternal mortality-rate was found to be diminished among the poorer classes, although the general idea is that it is lower among the better housed and better fed members of the community. Dr. Fairbairn discussed the social factors in these cases of maternal death and the influence of maternity insurance. He thought that if doctors did not attend cases of normal labour it would be difficult for them to keep themselves up in what one would call the ordinary normal labour. The health of the patient herself and all her social conditions had to be considered as being of the greatest importance. The relief of pain generally had brought about the consequence that pain is not as easily borne as formerly. The new situations of modern life must be considered, especially with regard to the maintenance of normal function. This applied to the problem of anæsthetics in labour.

Dr. W. H. F. OXLEY said that the Committee could not be blamed for not finding out the cause of maternal mortality. It was appointed first to advise upon the application to maternal mortality and morbidity of the medical knowledge at present available, and second to inquire into the needs and direction of further research work. It was the aim of the Committee to give the Government some practical method whereby a reduction in the maternal mortality could be effected and the direction in which further research should advance.

Prof. R. J. JOHNSTONE was concerned most with the education of the medical students, and this part of the Report was new. The problems were—can the teaching schools put these regulations into effect, and if so, will they produce a competent practitioner? These questions had been discussed by Prof. Munro Kerr elsewhere.

Lady BARRETT said the openers of the discussion had brought forward two important points in the Report. One was that only in 50 per cent. of the cases was the cause of death found. It was necessary, therefore, to look for the causes of sepsis elsewhere than in contact cases. The other factor was the woman herself, and this should be considered before any other. Practitioners were not necessarily all experts, but they should have reasonable skill, judgment, and knowledge. Would these regulations ensure the fulfilment of these conditions? It was difficult to get women to undergo antenatal supervision if it meant residence in hospital or attendance at a long distance clinic. The claims of her home were usually her first consideration.

Mr. W. GILLIATT said that the General Medical Council or the examining bodies do not insist on the present regulations being carried out with regard to 20 cases.

Dame LOUISE MCILROY thought the chief value of the Report was the crystallisation of the opinions of the representatives of societies and the obstetricians who gave evidence before the Committee. She believed that antenatal supervision should be carried out by trained obstetricians.

Mr. DONALD ROY said there was now an opportunity for making a very definite advance towards obtaining the requisite number of cases for medical students. The necessity for more obstetrical beds or facilities elsewhere must be pushed by the medical schools. The welfare of the patient was the first consideration when the administration of anæsthetics is considered. Women who were delicately nurtured had more fear

of the pain of labour than the women of the working classes, who were in closer touch with the reality.

Dr. G. W. THEOBALD gave the opinion that midwives should not be allowed to make vaginal examinations, and doctors should be restricted to forceps application only. Any other operation should be done by a specialist. More maternity hospitals are necessary throughout the country for the admission of complicated cases and for the training of students.

Prof. F. J. BROWNE reminded the meeting that the report was only an interim one. One of the chief problems was the cause of death in normal labour. He had a firm belief in Listerism as a prevention of puerperal sepsis. The whole scheme was based on a recognition of the fact that the psychology of women had changed and that she demanded premature interference because she could not bear pain well. Prof. Browne discussed the advisability of the direct responsibility of the teacher in signing up students for examination. The standard of training of the general practitioner was most important.

Mr. COMYNS BERKELEY believed that everything the Committee recommended should be carried out with regard to the training of medical students. The additional number of cases required could be found in the hospitals of the London County Council.

The PRESIDENT said that the report conformed very much with the opinions generally expressed by obstetric teachers.

Dr. EDEN and Dr. FAIRBAIRN replied.

SPECIMENS SHOWN.

Mr. JOHN H. HANNAN showed the following specimens: (1) Large bilateral Krukenberg's tumours of the ovary. (2) Endothelioma of the ovary. (3) A peri-urethral fibroma. (4) Dermoid cyst of the ovary with a basal-celled carcinoma in its wall. (5) Carcinoma of the body of the uterus from a young woman. (6) Carcinoma of the Fallopian tube. (7) Primary carcinoma of the urethra.—Mr. T. G. STEVENS, Mr. M. H. OLDERSHAW, and Mr. TREVOR DAVIES took part in the discussion. Mr. HANNAN replied.

REVIEWS AND NOTICES OF BOOKS

Diseases and Injuries of the Eye.

A Text-book for Students and Practitioners. Third edition by WILLIAM GEORGE SYM, M.D., F.R.C.S.E., late Ophthalmic Surgeon, Edinburgh Royal Infirmary. With 24 full-page illustrations, 15 of them in colour, and 58 figures in the text. London: A. C. Black, Ltd. 1930. Pp. 493. 12*s*. 6*d*.

EVERY text-book of worth, besides being a correct statement of the conclusions on diagnosis and treatment on which all authorities are agreed, is distinguished by a method of presenting the subject which reveals the author as having some originality of mind. Dr. Sym's book is an instance; it can be read, even by those who are familiar with the subject, with pleasure and profit. At the same time it is eminently practical from the point of view of the student. Omitting the usual introductory chapters on the anatomy and physiology of the eye for which the student must go elsewhere, and reducing optical formulæ and diagrams to the bare necessary minimum, Dr. Sym devotes his first chapter, on the general examination of the eye, to the varieties of pain of which patients complain, stressing the fact that in many of the most important affections of the eye no pain whatever is felt, and to the different ways in which sight may be impaired. Thus the student is made familiar from the outset with the four fundamental divisions of the sense of sight—light sense, form sense, colour vision, and binocular vision. Throughout the rest of the book the teaching follows traditional lines, being mostly confined to what a student, though not an advanced student, needs to know. In the chapter on iritis the term "rheumatic iritis" is retained, not because the author suggests that it is anything but very rare in association with acute rheumatism, but because it is not infrequently associated with chronic rheumatoid arthritis. His reference to those cases, where with true iritis there exists increased intra-ocular tension, is perhaps not very satisfactory, for the unqualified condemnation of atropine in these cases will not meet with universal assent among ophthalmic surgeons. The responsibility of treating these difficult cases should certainly be left to an expert where possible. We do not complain that in a book of this sort no reference should be made to the latest treatment for detachment of the retina, or to the latest theories of the intra-ocular circulation of fluid in connexion with the problems of glaucoma, but we deprecate the omission of any reference to arterio-sclerotic changes in the retinal vessels. The ability to detect these, though not easily acquired, is of very great importance in connexion with many problems which occur in general practice. We may add that the coloured illustrations are good.

A Treatise on Orthopædic Surgery.

Ninth edition. By Dr. ROYAL WHITMAN. London: Henry Kimpton. 1930. 45*s*.

THE fact that Dr. Royal Whitman's treatise on orthopædic surgery has passed through nine editions in the last 30 years is sufficient proof both of the excellence of the book and of the progress of orthopædic surgery. It now occupies 1085 pages and has 981 illustrations. The present edition has been thoroughly revised by the author, but the sifting process might have been more drastic, for much dead matter is included in the text, and the general surgeon or practitioner might well fall into some of the errors of his forefathers from lack of definite instructions. Thus, under the heading of operative treatment for calcaneus, Willett's operation of tendon shortening is still described, together with Willett's original directions (1880), whereas this operation has been universally abandoned. It is interesting historically and should be inserted in a paragraph on the history of treatment; it would, if placed there, serve a further useful purpose in preventing its rediscovery. In the chapter on tuberculosis of the hip no mention is made of the method of extension by body-weight on an inclined plane, used at Carshalton and elsewhere, and the citation of percentages and causes of death from statistics culled from deaths between 1877 and 1884 is only of historic interest. What we want to know nowadays are the results of open-air treatment and a comparison with those of 60 years ago. The benefits from extra-articular arthrodesis are difficult to estimate in this country, and a fuller account would be welcome from an author working in the sanatorium city as Hibbs. Dr. Royal Whitman's own operatic

of astragalectomy with backward displacement has many opponents both in England and America, and the inclusion of an account of late results by the author, illustrated by statistics, by post-mortem findings, and by radiography should help to prove its advantages. The chapter on fractures is incomplete, but we have a full description of the abduction treatment of fracture of the neck of the femur which will be associated always with the name of Royal Whitman. We hope in the next edition to find a note on the use of skeletal traction in orthopædic and traumatic surgery.

Traité de biocolloïdologie.

Tome I. *Pratique de Colloïdes.* Deuxième edition. Fasc. III: Mesures Capillaires et Electriques. By W. KOPACZEWSKI. Paris: Gauthier-Villars et Cie. 1930. Pp. 363–527. Fr.40.

M. Kopaczewski has embarked on an immense task. In a treatise of five volumes he proposes to describe the colloidal phenomena occurring in biology and medicine, and to apply the principles of colloid chemistry to those sciences. The first volume, Pratique des Colloïdes," is an enlarged and revised version of the author's "Théorie et pratique des colloïdes en biologie et en médecine," which was published in 1923. The first two parts of this volume were entitled "Propriétés mécaniques des colloïdes," and "Mesure des concentrations moléculaires et moniques"; the fourth part, "Mesures optiques et données numériques," has yet to appear.

In the third part, which consists of chapters on viscosity, surface tension, electrophoresis, and dielectric constant, the value lies in the excellent summary of experimental methods and technique. Some of these methods are not to be found in any other textbook, and many, including several devised by the author himself, are of remarkable ingenuity and interest. The sources of inexactitude and the methods used to combat these are clearly and logically described. If one or two productive methods are neglected it is doubtless because the author has preferred to describe those of most use in biology. M. Kopaczewski has made a special study of "l'analyse capillaire," and has reached interesting conclusions on a little-known subject.

At the beginning of each chapter there is a brief summary of several aspects of our knowledge of the subject. At the end of each chapter the author has made a conscientious effort to summarise the results of the application of these experimental methods to biology and medicine. This is an original idea and perhaps the most interesting part of the book, but it is obvious that the attempt has severely taxed both the ingenuity and the wide knowledge of the author. The redemption of his promise to elaborate these results in the succeeding volumes will be awaited with interest.

The Picture of Paris.

By LOUIS SEBASTIEN MERCIER. Translated with an introduction by WILFRID and EMILIE JACKSON. London: George Routledge and Sons. 1930. With 12 illustrations. Pp. 256. 12*s.* 6*d.*

Prof. Mercier was born in 1740, at the beginning of Madame de Pompadour's reign over Louis XV.; he was just of age when "Émile" appeared; he grew up with the leaders of the revolution, and he died the year before the battle of Waterloo. Judging from the interesting biographical details contained in the introductory sketch by the translators he responded freely to the political and social changes amid which he spent his life. A solid claim can be put forward for him as a prophet of the revolution, he became editor of a Girondist journal, as a deputy he voted against the execution of the King, but he escaped the fate of most of the Girondist leaders and saved his head. He said of himself that a man who came as near the guillotine as he did might well fall out of love with revolution, and as a matter of fact he became a reactionary under the Republican régime, and died just as the career of Bonaparte was closing in disaster.

Mercier prophesied that his book, "The Picture of Paris"—he wrote much else of many kinds—would be found useful in 100 years to come, because his observations would make a bond with the coming century; but the developments of machinery and transport, the discoveries in biology and chemistry, and, lastly, the European war, have so far removed the Paris of the eighteenth century from the Paris of the twentieth century that no bond can be recognised. Read, however, as a lively description of Paris before and after the revolution, every page has its historical interest or its amusing reminiscence, while many lights are thrown on the medicine of the period as well as on the morals of society. It goes without saying that the experienced translators have done their work well; they have caught the spirit behind the book, and have appreciated the close and whimsical observation which has accompanied the putting together of a desultory commentary. The illustrations are well chosen and reproduced.

Paterson of Hebron: "The Hakim."

By W. EWING, M.C., D.D. London: James Clarke and Co., Ltd. 1930. Pp. 256. 8*s.* 6*d.*

THIS book will appeal to all interested in medical missions and to those members of the Egyptian Expeditionary Force who served in Palestine, many of whom knew Dr. Paterson. It is a tale of hard, and at times exciting, work as a mission doctor in one of the most fanatical strongholds of Mohammedism—work which did much to raise the prestige of Britain in that part of the Near East. It is evident from the story that Paterson gained the affections of a turbulent and hostile people by his personal courage no less than by his professional skill; a strong man appealed to them. Among the medical matters dealt with, the notes on syphilis may come as a surprise to those who do not know the East. Interesting and authoritative light is thrown on many of Palestine's post-war problems, political, racial, and social, and the book is worth reading from this aspect alone.

Stedman's Medical Dictionary.

Eleventh edition of "A Practical Medical Dictionary." By THOMAS LATHROP STEDMAN, A.M., M.D., Editor of the "Twentieth Century Practice of Medicine." London: Baillière, Tindall and Cox. 1930. Pp. 1222. 35*s.*

THE new edition of this dictionary contains evidence of the accelerated movement of medicine during the past two years. All medical dictionaries tend to become more encyclopædic as they grow older, and the eleventh edition of Stedman contains 22 plates, more than 200 tables, 400 figures in the text, an appendix of drugs with their doses and uses, and a list of microparasites pathogenic for man and certain animals with their morphological and cultural

distinctions. Yet the dictionary contains the individual characteristics with which Dr. Stedman has long made us familiar. One of his primary objects when he began his work in 1908 was the purification of medical orthography, and after two decades of patient efforts he feels that this end has been nearly attained. He was, for instance, always opposed to the dropping of the terminal "e" from alkaloidal titles, thus doing away with the convenient distinction between alkaloids and glucosides, and he has now had the pleasure of seeing American medical journals unostentatiously restoring the missing letter. Definitions of words recently introduced into the physics of radiology have been included in the dictionary in anticipation of their adoption into medicine. We have no doubt that Stedman's dictionary will long continue its useful career.

Surgical Diseases of the Thyroid Gland.

By E. M. EBERTS, M.D., Professor of Surgery, McGill University; R. R. FITZGERALD, M.D.; and P. G. SILVER, M.D. Philadelphia: Lea and Febiger. Pp. 238. $3.50.

THIS book in small compass presents the surgical aspect of the goitre question succinctly, accurately, and in an attractive and readable fashion. The account is founded upon the study of 700 patients who have passed through the goitre department of the Montreal General Hospital. It should be read by all surgeons interested in goitre.[1]

The Mystery and Lore of Monsters,

With Accounts of Some Giants, Dwarfs, and Prodigies.

By C. J. S. THOMPSON, M.B.E. London: Williams and Norgate, Ltd. 1930. Pp. 256. 15s.

IMAGINATION from the beginning of history has been inflamed by gruesome descriptions of monsters, human, semi-human, and utterly inhuman, whose existence on earth has been recorded. Throughout this long period the art of writing and, later, that of printing have inflamed wild beliefs in what purported to be accurate reports of the appearances and exploits of monsters, and the awe and credulity displayed by the intelligentzia at various epochs have never ceased to puzzle the intelligentzia of their successors. To-day there may be found an astonishing readiness among highly educated people to believe in the existence of creatures that are structurally impossible. So a book by the curator of the historical section of the Museum of the Royal College of Surgeons of England ought to make valuable reading for the public, while it may well supply for medical practitioners categorical answers to questions which their clients love to propound as to three-headed nightingales, super-athletic cripples, and frantic hybrids. The book ranges through the age of mythology—the satyrs, cyclops, and headless men; through the sixteenth century when some sinister results of included twins received particular notice; and so to the time when, in the first half of the eighteenth century, the systematic study of abnormal formations commenced with the work of Caspar Friedrich Wolff. Wolff classified roughly variations of growth distinguishing between the dicephalus, the pygopagus, and the craniopagus, and explained the anatomy and development of joined twins. The influence of classical and mediæval superstitions was not countered then, and has not ceased to play its part to-day, but on the whole our grandparents regarded as the mysterious whims of the Creator much that we now know to be manifestations of faulty physiology. A very interesting chapter deals with the celebrated examples of this phenomenon.

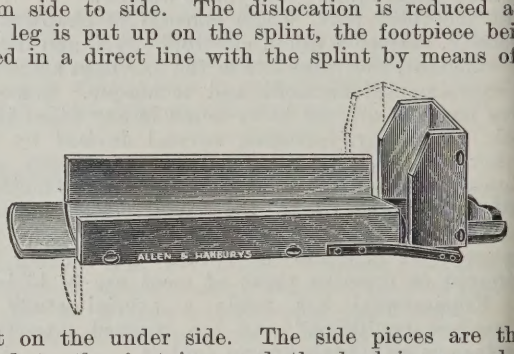
In the second part of the book the history of remarkable giants and dwarfs is fully set out and illustrated, and a large bibliography will enable the reader to pursue his studies along any line that appeals to his curiosity. As Sir D'Arcy Power says in an introductory note, this is a book which would have delighted the hearts of Samuel Pepys and Horace Walpole. It is true that the author's scientific accuracy goes far to explain away many picturesque stories, but his biographical notes will be found more interesting reading than ever were the mediæval legends with their patent incredibility. The book is very well illustrated, and in many libraries, scientific and otherwise, it should find a place as a work of reference.

[1] We regret that in a previous notice of this book one of the authors' names was misspelled.

NEW INVENTIONS

A NEW SPLINT.

THE illustration shows a new splint for Pott's fracture. It is a back splint, the lower end of which with attached footpiece, is capable of being moved from side to side. The dislocation is reduced and the leg is put up on the splint, the footpiece being fixed in a direct line with the splint by means of a



nut on the under side. The side pieces are then fixed to the footpiece and the heel is secured in position by cotton-wool padding. The side pieces are strapped together over the ankle-joint, further locking the heel. The nut is then loosened and pressure, exerted on the outer side of the movable portion by means of a spring acting along the outer side of the splint, maintains the complete reduction of the ankle-joint. The movable portion can be detached completely from the splint so that, when desired, the foot and leg can be put up in plaster-of-Paris without taking the leg off the splint. The splint can be used for either leg as the spring will fit on either side. The legpiece can be lengthened or shortened as desired, and the footpiece can be adjusted backwards or forwards on the movable portion. Detachable side splints are fixed to the leg-piece so as to anchor the leg firmly, thereby preventing twisting, and so making the pressure on the movable portion more effective. The nut securing the movable portion to the leg splint is made of wood so that clear X ray photographs can be obtained both anteroposteriorly and laterally, when the foot is fixed in position.

Messrs. Allen and Hanburys, Ltd., 48, Wigmore street, W., are the makers.

J. E. HEPPER, M.R.C.S., L.R.C.P. Lond.

THE LANCET.

LONDON: SATURDAY, DECEMBER 13, 1930.

BEIT FELLOWSHIPS.

THE death of Sir OTTO BEIT reminds us that the foundation of the fellowships for medical research which Sir OTTO established 20 years ago in memory of his elder brother was one of the conspicuous landmarks in the amazing progress which medical education and investigation have made in the twentieth century. Thirty years ago, if a young graduate wanted to devote himself to investigation in medicine or any of the medical sciences and keep himself alive, his path was by no means easy or assured. If he could get a teaching appointment his enthusiasm would probably make times and opportunities for research work, and many of the leaders of to-day could testify to the value of such an apprenticeship. But the number of teachers was limited and research scholarships for senior students were few and far between; there were the Grocers Company's scholarships in sanitary science, the John Lucas Walker studentship at Cambridge, the Radcliffe Travelling Fellowship at Oxford, and a few more plums which were eagerly sought after. All that is now changed; teaching posts are much more numerous and there are so many research scholarships in medicine and allied subjects that it is not always easy to find worthy recipients of all of them. The Beit benefaction marked the turn of the tide, and for the first time in this country the possibility of two or three or four years spent in research was open to more than a favoured or lucky few. The importance of this was two-fold. In the first place it gave a chance to the man with a clear faith and passion for investigation who had no money; somehow or other the best of these would generally survive and get what they wanted, but often enough by a very rough road which a Beit Fellowship made smooth and all the more productive. And in the second place the knowledge of the existence of such prizes has deflected the attention of many good men to the possibility of engaging in research, and a proportion of such have, on trial, found it to be their vocation. Looking back in recent years on the achievements and careers of those who have held his fellowships, Sir OTTO BEIT must have been very gratified at the results of his generosity. He had good cause. A few fellows have fallen by the wayside, a few have been choked with the cares of this life, but the majority have fruited well—professors, Fellows of the Royal Society, well-known investigators, a few clinicians. Under the loving care of Sir JAMES FOWLER—and who would not love a child with whose birth he had so much to do?—the trustees and their advisory committee have administered the foundation with singular success, adapting it wisely to the changing conditions which the Beit Fellowships themselves have done so much to alter. Research has now emerged as a profession, and there are senior fellowships with substantial emoluments for those who have proved worthy in the lower ranks. The intimate connexion between teaching and research is recognised by the fellows being allowed, even encouraged, to undertake a certain amount of undergraduate teaching in the schools in which they work—much to the benefit of all parties concerned. In one point only has the foundation failed—to get fellows of the right spirit who will work at real clinical medicine. And if anyone could tell them the solution of this troublesome problem, we are sure the trustees would do their best to adopt it.

RADIOLOGICAL DIAGNOSIS OF PLEURAL SYMPHYSIS.

IN the practice of artificial pneumothorax it is unfortunate that we have at our disposal no satisfactory preliminary method of determining whether the pleural space is free or limited by adhesions. The patient who has consented to this procedure and who is buoyed up by the hope that the method of treatment proposed will prove his salvation from lingering disease or early death will experience a severe disappointment if the induction fails. And though the disconcerted physician may with assumed cheerfulness refer to the event as one of minor importance and speak hopefully of "some other line of treatment" his assurances will seldom carry conviction. Thus, before an attempted induction of an artificial pneumothorax the patient should always be warned that success cannot be guaranteed. Physical signs or radiographic appearances may indeed provide arguments against the probability of a hopeful issue. In some cases a history of previous pleurisy may suggest that success is unlikely, in others preliminary radiograms may indicate the presence of fibrosis extending to and probably involving the pleura; or, without widespread pulmonary involvement, the parietal pleura may show evidence of thickening. But apart from experiment it is seldom possible to express a definite opinion as to the chances of success, and so long as the possibility of a fair measure of collapse remains the attempt should be made. For it sometimes happens that despite every indication of symphysis a free pleura will be found, and a lung which is apparently ensheathed in a thick and presumably universally adherent pleura will collapse uniformly at the first essay. Any evidence which throws a helpful light on the problem is thus of value and, despite the limited application of the tests proposed, a recent paper by E. SERGENT and J. VIBERT deserves attention.[1]

As these writers point out, a massive pulmonary fibrosis, whether due to tubercle, syphilis, widespread cancer of the lung, or

[1] Arch. Méd.-Chir. de l'Appareil Resp., 1930, v., 116.

pulmonary atelectasis and the partial collapse of the lung resulting from paralysis of the phrenic nerve, may, however produced, give similar appearances on the X ray film. Thus there will be opacity, often uniformly dense, involving the whole lung or one of its lobes on the affected side, displacement of the trachea and mediastinum, elevation of the diaphragm, and compensatory expansion of the opposite lung. In the differential diagnosis of the various conditions named it is necessary to distinguish between those in which there is a retractile sclerosis of the lung with involvement of the pleura and consequent symphysis of its layers and those in which there is no pulmonary fibrosis, no adherence of the pleura, for in the latter there is in many cases the prospect of a restoration of working capacity in the affected areas. In the examination of these cases it is important to note the static appearances as shown in radiograms, and to compare these with the moving pictures seen under the fluoroscopic screen.

In a typical case of retractile sclerosis and pleural symphysis the radiogram will show opacity of the lung fields, partial or total obliquity of the ribs, narrow intercostal spaces, the trachea drawn to the affected side and distorted in such way as to trace a sinuous course; in extreme cases even a well-marked S curve will be apparent. The diaphragm on the diseased side is elevated and its convexity is interrupted by small peaks or distorted by larger displacements. Examination under the fluoroscopic screen will show absolute or relative immobility of the affected side. If there is any movement it is of the slightest and tends to accentuate the diaphragmatic deformity, as the pleural adhesions responsible for the latter are dragged upon by attempted muscular contractions. On the healthy side the costal movements are exaggerated and the diaphragm gives strong "piston" thrusts. In atelectasis—whether due to a foreign body obstructing a bronchus, to stricture, malignant or innocent, or to post-operative causes—dullness of the affected lung and compensatory expansion of the healthy lung will also be seen. As in the previous group the mediastinum will be displaced towards the affected side and the diaphragm will be elevated, but certain striking differences are apparent. The diaphragmatic dome is smoothly rounded, there is no looping or tenting. Under the fluoroscopic screen, though diaphragmatic excursions may be limited, some movement is apparent. Further, the displaced trachea retains its normal direction, it remains straight, not sinuous. Obviously, if the atelectasis is the result of a foreign body or of a plug of mucus, complete restoration of the normal appearances will follow removal of the obstruction. When diaphragmatic elevation is due to paralysis of the phrenic nerve there can be no muscular contraction of the affected side, but in the absence of adhesions a see-saw movement may be observed under the screen, contraction and hence depression on the sound side being correlated with an upward movement on the diseased side. In this condition the intercostal muscles endeavour to compensate for diaphragmatic inertia by vigorous contractions.

THE PLAIN MAN AND THE EXPERT.

THE headmaster of Harrow has been praising medicine as an exact profession; for doctors, he says, base their diagnosis on a careful examination of all the factors in the case. This is pleasant hearing, of course, but scarcely true. Does any practitioner really give careful attention to all the factors affecting his patient? Certainly not; all he does is to note some of those outstanding in the light of his experience. If one of these cannot be neatly named, he calls in an expert to look at it more closely; but a complete examination of even one factor is never possible, because every factor is infinitely divisible until we reach the growing points of science. This inevitability of ignorance ought to be recognised for the good of the soul, but it is fortunately remote from the problems of everyday practice. Here a half-truth is much better than none at all, and everyone knows that patients ought to get much more benefit from the information already available. To justify Mr. NORWOOD'S description, the profession must make better use of its experts. As the tree of knowledge grows the practitioner more and more requires the helping hand of specialists who have climbed a little further up some particular branch. At the same time, with all this climbing, we must take care that nobody drops the patient.

Some of the dangers of specialism were well described by Dr. A. E. BARCLAY in his presidential address to the British Institute of Radiology last week, and printed on the first pages of this issue. He showed its bad effect on teaching and research and indicated the increasing difficulty of being anything more than a specialist within a specialty. But the problem of the expert and his uses is not confined to medicine alone; it is, indeed, an essential problem in government and most other branches of human endeavour. The time has come when ordinary people frankly admit their hopeless ignorance of gold standards and electricity, and most of the other fundamentals of civilised life, and there is a powerful tendency to let executive decisions rest with the men who understand these matters. The expert to-day, says Prof. HAROLD LASKI, is accustomed to a veneration not very different from that of the priest in primitive societies, for he exercises a mystery into which the uninitiated cannot enter. As professor of political science of the University of London, Mr. LASKI is chiefly concerned with this tendency as traceable in economic and social life, but his reflections in the December number of *Harper's Magazine* contain lessons which we may well apply to the work of our own profession. His main thesis is that the expert's opinion should never be final; decisions must ultimately rest with the amateur, "the plain man," who alone can give them coherence and proportion. For special knowledge and the highly trained mind produce their own limitations. The expert sacrifices the nicety of common sense to the intensity of his experience. He dislikes the appearance of novel views. He often fails to see his results in their proper perspective. He is apt to deny that truth can possibly be found outside

the borders of his own private caste, and is hostile to views not set out in terms he has been accustomed to handle. Specialism, says Prof. LASKI, seems to breed a horror of unwonted experiment and a weakness in achieving adaptability, both of which make the expert of dubious value when he is in supreme command of a situation. He tends to make his subject the measure of life instead of making life the measure of his subject, and the result is often a confusion of learning with wisdom. "The fixed person for the fixed duties (Prof. LASKI quotes Prof. WHITEHEAD), who in older societies was such a godsend, in the future will be a public danger." Prof. LASKI would argue that the more expert such fixed persons are, the more dangerous they are likely to be. The wisdom needed for the direction of affairs is not expert technique but a balanced equilibrium. It consists not in the possession of specialised knowledge but in power to utilise its results at the right moment and in the right direction.

The plain man, in medicine, is the general practitioner. The specialist may think him an unskilled amateur, and the practitioner may be fully aware of his limitations; but he retains executive command of his cases for much the same reason as inexpert Cabinet Ministers retain command of their departments. If this is right and wise—and that is a fair deduction from Prof. LASKI'S words—let us frankly confess it and train men properly to undertake executive work and not something quite different. "A very broad basis of education," Dr. BARCLAY says truly, "is essential for critical appreciation of specialised knowledge," but the present plan of instruction is nothing so much as a scramble among teaching departments—the winner being allowed to inflict as much information as he can get into the time. Dr. BARCLAY is right in saying that the student could be just as adequately prepared for his life's work in a far shorter period, and he is right again in pointing the way to this end. *Eliminate all technique*, he says, except for those who intend to specialise. Reduce the student's burden by placing the common good before departmental interest. But, above all, he might have added, remember that nothing is to be gained by trying to turn the executive practitioner—the plain man—into an incompetent expert in every division of medicine.

WOUNDS AND MAGGOTS.

INDIVIDUAL surgeons learned much during the late war about the treatment of the infected wound; there was then enough material to test and evaluate different methods almost with laboratory exactitude. Such experience no longer falls to the lot of any one surgeon, although there must be a large total of heavily infected wounds scattered over the hospitals of the country. There may now be a certain danger that through lack of equipment or of imagination some of the lessons of the war may not be applied. Primary suture of gun-shot wounds, after excision of damaged tissue, was proved to be safe within a period of six to eight hours after receipt of injury, and the same holds good for motoring and other accidents, most of which receive attention within that period of time. In a number of cases primary suture fails or is impracticable and the result is an infected wound. Recently certain interesting views have been advanced concerning the treatment of such wounds, particularly when complicated with fracture of bones. Mr. A. J. WALTON has been led to regard[1] extensive surgical procedures for the treatment of sepsis as wrong; it is now, he says, his custom to wait until the sepsis becomes localised and then to deal with the focus. Dr. H. W. ORR, of Nebraska, advocates[3] treating compound fractures in a plaster cast, to insure absolute rest to the injured limb, the wound being dressed with vaseline gauze which is allowed to remain undisturbed. Dr. LORENZ BÖHLER, drawing on his experience at an accident hospital in Vienna, while agreeing in the prime importance of absolute and continued rest, prefers to leave the wound exposed to the air with formation of a protective scab to form.

Neither of these methods, however, successful as each undoubtedly may be, constituted a quick way of converting a septic wound into a clean granulating one in which secondary suture, if required, can be performed. Of the methods which have been devised to achieve this result the best known is that of Carrel and Dakin; but Dakin's solution probably achieves its results by virtue of its proteolytic power, owing to which the wound is freed of all dead tissue and therefore of microbes. Mr. E. G SLESINGER pointed out again at a recent discussion[2] that in Nature a similar result is achieved by the growth of fly maggots in an infected wound. During the war it was a common observation that the men who had lain for many hours or days in front of the lines, and whose wounds were heavily infected with maggots, often did surprisingly well. Maggots deliberately planted into a wound, provided they are kept from encroaching on the skin by a wire gauze cage fixed with plasticine, will clear an infected wound of dead tissue within four or five days. At the end of that time, if the maggots are demobilised by chloroform vapour and gently scraped away, a wound is left covered with small healthy granulations, beneath a layer of mucoid slime which can be picked off the surface with forceps. Whatever æsthetic objections may be felt to such a treatment, it is found in practice that the maggots can be introduced without the knowledge of the patient, and provided they are kept from the skin surface he is not conscious of their presence. This artificial myiasis does, in fact, offer a method equivalent to surgical débridement but applicable to the heavily infected wound, and capable of cleaning a complicated area which could not be dealt with by surgical means. Dr. W. S. BAER, of Johns Hopkins, has used the method in the treatment of osteomyelitis, septic sinuses, and such conditions with satisfactory results for over two years, and it would seem that, as an adjunct to the treatment of septic wounds, maggots are worthy of the serious attention of surgeons.

ANNOTATIONS

THE COMMISSION ON NURSING.

THE first meeting of the members of the Commission was held on Monday last in the Office of THE LANCET, when Lord Crawford presided over a full attendance. The terms of reference were explained and the first directions of the work, as defined by those terms, were settled. The favourable reception of the inquiry by the general and medical press was reported, and the attention of the meeting was drawn to certain of the many communications which had been received. It was announced that the inquiry would be pursued in all representative centres, and it is hoped to secure coöperation and to collect information on the various problems involved.

Any organisation or individual wishing to provide evidence for the Commission to consider, or to make proposals relating to the improvement of conditions of service of the nursing profession, is asked to communicate with the hon. secretary at THE LANCET Offices, 7, Adam-street, Adelphi, London, W.C.

INTRACRANIAL INJURY DURING BIRTH.

A RECENT meeting of the Massachusetts Medical Society[1] was devoted to the effect on the nervous system of injury during birth. As an obstetrician Dr. F. C. Irving frankly resented the common assumption that intracranial hæmorrhage is due to bad obstetrics. The cardinal sign of intracranial hæmorrhage, he says, is disturbance of respiration, the later signs being apathy, refusal to suck, pallor, and a tense fontanelle. At the Boston Lying-in Hospital of 182 autopsies from all causes, 73 (40 per cent.) revealed intracranial hæmorrhage as the cause of death. In 23 of these cases labour had been normal; 23 were delivered by the breech, 21 with forceps, and 3 by Cæsarean section. These figures suggest that no particular obstetric procedure is especially responsible. Dr. Irving maintains that asphyxia is a true cause of hæmorrhage, even in the absence of trauma, and infants showing signs of intra-uterine asphyxia can sometimes be saved, he believes, by Cæsarean section.

Dr. Donald Munro gave further details of his series of 117 cases of cranial and intracranial injuries (THE LANCET, 1929, i., 31). In no less than 54 of these the infants were first-born. Cerebral œdema without macroscopic hæmorrhage was a common and significant finding, and microscopic examination usually showed some associated intracortical hæmorrhage. On further analysis of his series Dr. Munro finds that the most frequent symptoms were hypertonicity, abnormal or poor cry, cyanosis, and failure to nurse; tense fontanelle was slightly less common. Hypertonicity was relatively frequent in the cases which survived, and cyanosis in those which died. Less common symptoms, which were associated with high mortality, were flaccidity and pallor, often with apathy and failure to suck; in these cases the pressure of the cerebro-spinal fluid was below normal. These symptoms are indicative of surgical shock, and occur typically with gross meningeal damage. In the absence of surgical shock all cases with cerebral œdema or hæmorrhage showed increased intracranial pressure. Dr. Munro recommends no active treatment during the stage of surgical shock, except possibly rectal magnesium sulphate. When surgical shock is absent, the rise of intracranial pressure should be combated by repeated lumbar puncture, unless there is evidence of hæmorrhagic disease, in which case the bleeding and clotting times should first be brought to normal.

Dr. Randolph Byers recognises two types of nervous lesions in infants: (1) due to strain on supporting structures with rupture of the vessels which they contain, as described by Eardley Holland; and (2) small intracerebral hæmorrhages as described by P. Schwartz. Both types are common. His series of 12 cases illustrating the variety of situations of birth trauma deserves detailed study. Some of them lend confirmation to the work of Crothers and Putnam on spinal trauma in breech deliveries; in one case he is able to demonstrate the morbid anatomy of this condition in a child which died of intercurrent disease in the fourth month. In most of his cases of intracranial hæmorrhage the bleeding was considered to be mainly intracerebral, especial attention being paid to cases of this kind in which hyperkinesis subsequently developed, and in which it is suggested that the lesions involved the basal ganglia. Dr. Byers is in general inclined to attribute the pathogenesis of cerebral lesions met with in childhood to natal rather than prenatal causes.

A paper by Dr. G. B. Fleming and Dr. Ellen Morton,[2] of the Royal Maternity Hospital, Glasgow, can usefully be compared with those read at the Massachusetts Medical Society. They take the view that the clinical signs of cranial hæmorrhage are unconvincing, and that the most reliable evidence during life is obtained from the presence of a xanthochromatic spinal fluid. They think, however, that *intracerebral* hæmorrhage is rare, and they infer from the presence of xanthochromatic fluid that the hæmorrhage is meningeal—an assumption hardly supported by sufficient evidence. An account is given of 103 infants suffering from intracranial hæmorrhage, of whom 50 died before discharge and 7 subsequently. The duration of labour showed no significant relation to the mortality, but labour was abnormal in 50 per cent. of the cases, as against 27 per cent. of all women delivered in the hospital. In the fatal cases tentorial tears were the commonest lesions, being found in 16 out of 39 autopsies. Of the non-fatal cases 33 were examined after they had passed the first year, and only 5 of these were suffering from any defect.

INTESTINAL FLORA.

THE bacteriology of the more accessible parts of the alimentary canal has long been studied and recently intubation has made it possible to take cultures from the gastric and duodenal fasting contents. But, apart from operation and autopsy, the nature of the flora lower down has only been deduced from examination of the fæces, and in clinical work this has many fallacies. Certain bacteria, such as those of the typhoid group, are known to cause disease; but of the hosts of other inhabitants of the intestinal tract it is hard to say which are real parasites and which are of no pathogenic significance. Moreover, owing to drying in the colon many bacteria are dead before the fæces are voided. The Einhorn method of intubation which was introduced for therapeutic purposes offers new means of taking

[1] New Eng. Jour. Med., Sept. 11th, p. 499.

[2] Arch. Dis. in Childhood, October, 1930, p. 361.

samples of intestinal flora at various levels. The perforated end of the fine rubber tube swallowed by the patient is sealed in collodion sacs so that no fluid can enter until the end is in the situation required, as determined by the length of tube paid out, controlled by X rays to preclude the tube being coiled on itself. The collodion sac is burst by blowing a little sterile salt solution through the tube, and a sample of intestinal contents is sucked in. The tube may now be washed through with iodine and sterile salt solution and withdrawn to a higher position in the alimentary canal where a further sample is obtained. In an investigation just recorded[1] patients with high gastric acidity were found to have low duodenal bacterial counts, whereas in those with low acidity duodenal counts were high. A series of arthritic cases showed in the main a fermentative flora with *Streptococcus viridans* present in all parts. The patients with enteritis and cholecystitis had a putrefactive intestinal flora. The bacteria in the throat, stomach, duodenum, and intestine varied greatly in the same patient.

POST-OPERATIVE PLASTIC SURGERY.

AT a meeting of the Section of Laryngology of the Royal Society of Medicine on Dec. 5th, Mr. E. Musgrave Woodman made a communication on plastic repair after operations on the upper jaw. In planning the original operation, he said, there are certain points which tend to prevent or minimise deformity, and it is an advantage when the surgeon who performs the first operation is also able to undertake any plastic procedures which may be required later. The old transverse incision below the eyelid must be relinquished, for it is often followed by unsightly baggy swelling of the lid; Trotter's incision through the inferior fornix of the eye may be used, but Mr. Woodman prefers to begin his incision in the eyebrow and extend it down the side of the nose. To prevent dropping of the eye-ball, the infra-orbital margin of bone should be retained if possible; failing this, the suspensory ligament should be left. Perforation of the palate is not regarded as a deformity; on the contrary, such an opening should be left in every case for proper inspection of the operation area. This opening is controlled by a denture, held in position by two soft rubber processes which project into the aperture. Indeed, skilled dental assistance is of great value; a temporary plate can be made and fitted a few hours after operation, keeping the dressings in the cavity clean and enabling the patient to eat and swallow easily. A stent attached to the plate can be used to fill out the hollow left by removal of bone; and when a large hole in the face remains, unsuitable for repair by plastic operation, a vulcanite shield can be attached to the plate to fill the gap and painted to match the skin of the face. Mr. Woodman illustrated his paper by photographs showing methods of repair by means of forehead flaps and of tube-grafts taken from the chest. In a second communication Mr. Lionel Colledge dealt with the repair of pharyngeal defects after operation for removal of malignant tumour. Such openings usually occur as a complication after total laryngectomy and lateral pharyngotomy; they may be accidental, the result of wound-infection, or they may be produced deliberately, when so much of the pharyngeal wall has been excised that it cannot be closed securely, and is advised when X rays have been used on the pharynx. In closing these pharyngostomes it is useless to slide a single flap across the opening, having an inner raw surface exposed to contamination; the gap should be closed by a double layer of tissue which presents a lining of skin or mucous membrane facing inwards and of skin facing outwards. Skin flaps are dissected up and turned inwards to reconstruct the tube; this leaves a large raw surface which is covered by a flap taken from the loose skin below the horizontal ramus of the lower jaw and rotated into position. Four patients were shown to illustrate Mr. Colledge's paper.

In the discussion of these papers the opinion was expressed that recent advances in plastic surgery permitted operation on more extensive tumours than formerly, with the prospect of leaving the patients in a tolerable condition. The growth of hair upon the inturned skin flaps was inclined to be troublesome in the nose and mouth as well as in the pharynx; X rays were not considered reliable in preventing this, and in a recent case Mr. Colledge had had all the hair follicles epilated by diathermy before the plastic operation.

THE WIDAL TEST AGAIN.

THE exaggerated claims sometimes made for this test and the sweeping condemnations to which it is also subject have prompted Major J. A. Manifold, R.A.M.C., to estimate its value in more accurate terms.[1] In his attack upon the subject from the point of view of diagnosis of the enteric group and differential diagnosis of the paratyphoids, Dr. Manifold has a wealth of accurate data to draw upon. His first favourable circumstance lies in the existence of an ideal experimental animal—the soldier, white or native, of the Indian army who willingly reports sick within the first week of disease and thereafter submits to as many tests as are required to establish bacteriological and serological diagnosis. The results thus gathered are comparable owing to the second favourable factor which is the uniform standardised technique used in the army laboratories in India. Prof. Dreyer's methods are followed by workers all similarly trained, and so the conditions for optimum results are fulfilled. Dr. Manifold was able to analyse 227 bacteriologically proven cases of enteric fever, of which 152 were due to *B. typhosus*. When on an average 4·39 tests per case had been done 64 per cent. of these would have been diagnosed and classified on their serum tests alone. If the group is subdivided, of 84 severe cases, 75 per cent. could have been diagnosed, of 68 mild cases 50 per cent., and of 24 very mild ones only 37·5 per cent. would have been detected. As an instance of these mild infections Dr. Manifold mentions patients who have been admitted to hospital for an unknown pyrexia, a blood culture made, the patient discharged as well, and readmitted a few days later when results of the culture became known. It is interesting to compare the figure for the whole group 64 per cent. with A. Pijper's 60 per cent. in bacteriologically proven cases. The former is the result of 4·39 tests per case, the latter the finding at the first examination and of course points only to enteric group. The number of complete failures is about the same. Dr. Manifold reaches the conclusions that no serological test can replace careful, repeated bacteriological examinations; that in average severe cases, the Widal, practised with Dreyer's cultures and manipulations, remains a valuable aid to differential diagnosis; and

[1] Jour. R.A.M.C., June–August, 1930.

that the chief field of usefulness for Felix "O" suspension may lie in the detection of mild and abortive cases if experience proves it to be a sensitive indicator in this particular group. Concerning the fluctuation of group agglutinins he dissents from accepted teaching on the subject. With these conclusions all will agree but the civilian practitioner will no doubt protest, as Dr. Manifold has anticipated, that his patient will not only refuse to put up with four or five vein punctures during 30 days of disease, but also he can seldom afford it. Felix's improvement on the test which claims greater certainty in achieving all objects by even one examination than does the old method in five, deserves to be tested as completely, and one hopes that Dr. Manifold will direct that this be done in his vast laboratory.

VACCINE TREATMENT OF WHOOPING-COUGH.

THE high mortality from whooping-cough reported in many parts of Western Europe, especially during the last few years, has stimulated search for remedies. Among those recommended are injection of ether, exposure to ultra-violet light or to X rays, and a great variety of drugs, of which luminal appears to be the latest. At the same time interest has revived in the possibility of vaccine treatment. In introducing this subject Dr. Philipp Leitner[1] points out that early diagnosis is essential whatever the treatment employed. He lays it down as a principle that when a child with a cough, free from fever, without catarrhal symptoms or evidence of inflammation (such as otitis, furunculosis, or pyuria), and with no enlargement of liver and spleen (such as would suggest, for example, leukæmia or malaria), has a leucocyte count of over 12,000 per c.mm., then that child has whooping-cough. The diagnosis is strengthened if the white cell count is still higher on being repeated after two to three days. This method of diagnosis, according to Leitner, helps to exclude enlarged bronchial glands and spasmophilia as the cause of a spasmodic cough. His own experiences with the use of vaccine in treatment are limited to 20 cases, but these he studied in some detail. He employed a highly concentrated vaccine specially prepared from Bordet-Gengou bacilli grown on blood-agar and killed with carbolic acid. This vaccine was supplied in phials containing 3, 4, 6, and 8 thousand million organisms per c.cm. and was usually given in six doses at two to three day intervals, each of the first four doses being 1 c.cm. of the strengths mentioned and the last two obtained by combining the solutions supplied to give 9 and 12 thousand million organisms respectively. After the first two injections the number of coughing attacks was considerably lessened and individual attacks were shorter in duration and less severe. Local reactions were never seen after the early smaller subcutaneous injections, and even after the later larger injections, which were given intramuscularly, no serious troubles were experienced except in one case where a slight inflammatory infiltration occurred at the site of injection together with a generalised eruption of roseolar type. In this case, however, as in all the others, favourable results were obtained. Even in quite small infants not only were the large doses of vaccine well borne but the usual period of duration of whooping-cough was curtailed. This was obvious after four injections, but in three older children after four doses of vaccine there was a slight relapse which was promptly cut short by the usual fifth and sixth dose. Other auxiliary methods of treatment may be combined with the vaccine in these cases, but in Leitner's opinion the short duration of the disease, 10 to 14 days, under the influence of the concentrated vaccine makes drugs unnecessary, although in several cases he gave luminal during the night. Four cases in which the treatment was not begun until the disease was well established were benefited by the vaccine, but the illness was not noticeably shortened.

DOUBTFUL GROWTHS OF THE BLADDER.

MALIGNANT growths of the bladder have always presented many difficulties to the surgeon, and their proper treatment is still uncertain. This was evident in the discussion on the presidential address with which Mr. Sydney Macdonald opened the present session of the Section of Urology of the Royal Society of Medicine.[1] His title was Results of Partial Resection of the Bladder for Carcinoma, but he found occasion to consider the treatment of other growths as well. Incidentally, he pointed out that their scientific classification is by no means easy, since many which clinically seem innocent are shown by microscopic section to be malignant, and vice versa. He himself, as a working rule, divides growths roughly into three groups: those probably benign, those certainly malignant, and those doubtful. Of all methods of treatment he prefers resection, and he uses diathermy only for growths appearing innocent and small in size. Speaking of those which are certainly malignant he said that he had notes of 120 cases, of which only 35 were operable when they first came for examination. The large number of inoperable cases was very striking, and since most of the records came from his private practice and did not include cases seen in his out-patients' department, the percentage of inoperable cases was even higher than these figures indicated. Among 44 patients who submitted to partial resection of the bladder, and of whom nine could not be traced, six died in the nursing home or hospital as the result of the operation. Of those who survived operation, 15 died within the next three years, leaving 14 alive and well after that period, or 31·8 per cent. of those operated on. Mr. Macdonald concluded his address by inviting opinion about the best method of treatment of growths of doubtful nature, and the speakers who followed were divided into two groups—those who considered that diathermy was a useful alternative to resection in the treatment of growths not obviously malignant, and those who insisted on excision. Mr. Ralph Thomson was strongly inclined to extirpation with the knife. Although he did not go so far as to say that diathermy may not be useful, he thought that three-quarters of the surgeons who use diathermy are not expert bladder operators. One of the chief disadvantages of diathermy treatment was that a vast amount of tolerance on the part of the patient is required for success. Mr. Jocelyn Swan agreed that diathermy should only be used for small and unmistakable papillomata. Mr. Zachary Cope and Mr. F. M. Loughnane, however, were both disposed to think that the scope of diathermy is greater than previous speakers indicated, and Mr. E. W. Riches quoted two cases of inoperable growth in which palliative treatment by diathermy was followed by comparatively good results. In reading the report of discussion, it is interesting to note that treatment by deep X rays and by radium received little notice. Mr. Macdonald recommended X ray therapy as a prophylactic measure

[1] Proc. Roy. Soc. Med., 1930.

after the excision of a malignant growth, and Mr. Zachary Cope quoted a case of malignant bladder improved by diathermy followed by insertion of radium. It must be borne in mind, however, that the discussion was primarily one on resection of the bladder and on the treatment of growths of doubtful nature. Had carcinoma been under consideration it is probable that more would have been said of ray therapy.

FOG PANIC ON THE MEUSE.

LAST week the first cold snap of winter brought with it the customary blanket of fog over the North Sea and neighbouring coast lands. Sea passages were slow and dangerous, communications were held up, and the depressing effect on the lives of aging persons will soon be manifest in the weekly returns. But something more than this occurred in the valley of the Meuse above Liége. At Engis and several other villages on the river level a number of deaths occurred among men and animals which were so grouped and so rapid as to give rise to something of a panic. Other agencies than those of fog and cold were brought in to explain the 64 deaths within so small an area. There was talk of poisonous fumes from local factories kept down by the fog bank, and of some deadly local epidemic; even wilder thoughts were current in the villages. Local anxiety was such that the inhabitants barricaded themselves and their domestic animals into their houses. When the fog lifted saner counsels prevailed, and a local inquiry at Engis last Sunday came to the conclusion that fog alone was sufficient cause of the deaths and that noxious gases were in no way connected with the occurrence. Our own Ministry of Health has received an assurance from the Belgian health authorities that the deaths were not due to any communicable disease. Inquiry is still proceeding, but it has been ascertained that the victims for the most part were old or feeble, and that, of the five deaths in one commune, two were suffering from heart disease, one from tuberculosis, one from asthma, and the fifth from obesity. Post-mortem examination of cattle has shown pulmonary œdema and nothing more.

Without anticipating the findings of the Commission of Inquiry, it may be recalled that the Meuse valley at that point is deep and sheltered, and that cold air settles in the bottom of such a valley, producing conditions of rigour which are known little or not at all in wider valleys such as those of Thames and Clyde. In this country there is scant evidence that fog itself has appreciable effect on the respiratory death-rate, but if the fog is associated with a low temperature the effect on the adult death-rate makes itself evident at once. The bad February of 1880, when hoar-frost, low temperature, and fog figured in the Greenwich records, witnessed a sharp rise in the death-rate in the St. Pancras and Islington area. The factors are discriminated in a careful analysis of the figures for the two London boroughs over a period of 27 years made by Mr. W. T. Russell at the National Institute for Medical Research and published in our columns.[1] Of the two factors of cold and fogginess, the former was definitely shown to exercise the greater influence. Knowing the temperature and the amount of fog Mr. Russell was able to predict (within a marginal error of 30 per cent. or so) the mortality from respiratory disease for the succeeding week. The late Dr. J. B. Russell, health officer for Glasgow, used to maintain that during the winter every city is in danger of a catastrophe if a combination of frost, fog, and still air occurs for days together. It seems that these conditions united on the Meuse to produce so terrifying a situation last week.

MEDICAL USES OF RADIUM.

THE summary of results of research on radium during 1929 [1] continues the series published annually by the Medical Research Council, and is arranged more conveniently than its predecessors. It gives a rather full account of the treatment of œsophageal and rectal growths, about which there is as yet no general agreement. The methods of radium application for cancer of the cervix, breast, and tongue are by now almost standardised, the techniques of the various schools differing only in details such as quantity and time. Growths in the œsophagus and rectum, however, are difficult of access, highly resistant to radium, often complicated by bacterial infection, while damage to the surrounding tissues may be a serious feature in irradiation treatment. There is now general agreement that cases of idiosyncrasy to radium are encountered from time to time, but another question that has often been asked still meets with no definite reply: "Can radium ever stimulate malignant tissue to more active growth?" In one of the cases of mammary carcinoma reported by the Middlesex Hospital it is suggested that the progress of the disease was accelerated by the treatment. The woman's history is given in full, with two microphotographs. It is impossible to say whether the evil effect was due to the opening up of fresh channels by the needles or to the action of the rays, either on the malignant cells themselves or on the surrounding tissues of the host. The answer to this question is obviously one of the very first importance for radium therapy.

The techniques under trial for œsophageal carcinoma at the Middlesex Hospital are as follows. For four cases of post-cricoid growth the radium was inserted on or in the prevertebral muscles and against the side of the gullet in eight or ten 2·2 cm. needles each containing 0·5 mg. of radium element. They were left in for a week or ten days. Twelve cases were treated by intra-œsophageal application, either with a special silver radon applicator like a Souttar's tube or else by means of Muir's seeds on a Souttar's tube. Four more cases were treated by thoracotomy, radon seeds being inserted sub-pleurally after collapse of the lung. At St. Bartholomew's Hospital some progress has been achieved by exposing the lumen to needles applied on a Symond's tube. The opinion at Birmingham is that the external approach is only favourable when the growth is either in the neck or the lower part of the thorax. The operation is risky, in contrast to the intra-œsophageal approach, which has shown no immediate mortality.

For the rectum St. Bartholomew's Hospital prefers radium needles; in very advanced cases relief has been obtained by radon seeds inserted through the peritoneum, the anus, or the peri-anal skin, sometimes combined with posterior barrage. The Middlesex Hospital reports partial success with buried radium, without any operation. St. Mark's Hospital comments on the contrast between the satisfactory results of radium treatment of squamous

[1] Special Report Series No. 150. London: H.M. Stationery Office, Kingsway, W.C.2. Pp. 32. 9*d*.

carcinoma and the variable response of columnar-celled tumours. The Birmingham report stresses the value of colostomy, both for its therapeutic effect and for the possibility it affords of recognising hepatic metastases. Irradiation has been given chiefly by perineal puncture and needles, but the coccyx has also been removed to expose high growths.

A SURVEY OF PSITTACOSIS.

THE collection into one official handbook[1] of the results of recent research on psittacosis, much of which was originally recorded in our columns, will be a convenience to future workers. The history, clinical aspects, and pathology of the disease have been dealt with by Dr. S. Levy Simpson. Experimental observation on the ætiology are described by Dr. S. P. Bedson and Dr. G. T. Western, while Dr. Mervyn Gordon gives an account of virus studies in relation to psittacosis. Dr. G. L. Sturdee and Dr. W. M. Scott, medical officers of the Ministry of Health, have woven the whole into a connected story, contributing an introduction giving a brief account of the events leading to the present interest in psittacosis, and a considered review of the epidemiology as at present ascertained. The administrative action taken in this and other countries to control or prohibit the importation of birds of the group known as psittaciformes is also set out, while appendices include statistical tables, full notes on typical cases, and suggestions for the transport and keeping of birds. The fact seems to be established that the causal agent of psittacosis is a filtrable virus, associated constantly with the presence of a minute cocco-bacillary body. The possibility of producing an active immunity by means of a formolised vaccine is being considered, the one experiment on these lines which has so far been carried out having given encouraging results.

THE NEW MERCURIAL DIURETICS.

THE value of Novasurol and Salyrgan was discussed at a meeting of the Section of Therapeutics of the Royal Society of Medicine on Dec. 9th, when Dr. Philip Hamill presided. Dr. Evan Bedford and Prof. F. R. Fraser were able to testify to the efficacy of novasurol as a diuretic, but Dr. Strickland Goodall thought that the reduction of œdema after its use is due to loss of fluid by way of the alimentary canal. Often, he said, this drug produces a severe toxic diarrhœa, and he handed round two specimens showing sections of gut in which the mucous membrane was inflamed and sloughing as a result of the exhibition of novasurol. Dr. Bedford, however, was able to give a reassuring account of salyrgan, which he had first begun to use 18 months ago, and which he regarded as considerably less toxic than novasurol. His method is to give 2 c.cm. of the 10 per cent. solution diluted with 10 c.cm. of sterile saline, by intravenous injection; in this dilution he has never seen thrombosis of the vein following the introduction of the drug. In his opinion, it is unnecessary to stop digitalisation while salyrgan is being given, and he always accompanies the treatment with grs. 15 of ammonium chloride given by mouth three times daily to aid the diuretic action. Fluids should be restricted to daily intake of ℥xx. to ℥xxx. Using this technique, among 27 cases of cardiac failure with œdema he has only had three failures, and the three patients in question were moribund at the beginning of treatment. He quoted several of his cases in which the diuresis following salyrgan was marked; some of them lost 40 lb. or more in weight in a month. So far, he said, no toxic effects have been observed, but he thinks the chief value of the remedy is in cases of cardiac œdema. Though it is supposed to act by diminishing the affinity of the tissue colloids for water and sodium chloride, there is some evidence that salyrgan also has a direct action on the kidney, and for that reason its use is less desirable in œdema due to nephritis. While none of the other speakers could produce quite such dramatic results as Dr. Bedford, several were able to quote cases where salyrgan had promoted diuresis and reduced the œdema in cardiac cases. Dr. D. H. Kotthoff, of Vienna, stated that many good results had followed its use among cardiac cases in Austria. It was agreed by the majority that both novasurol and salyrgan should be avoided in œdema of renal origin; but Dr. Izod Bennett held that, although they are dangerous where the kidney is seriously injured, in cases which show gross pitting œdema with a normal blood pressure and blood-urea, salyrgan may be useful and is probably safe. Dr. Kotthoff shared this view. The use of salyrgan in the diagnosis of Ménière's disease was mentioned by Sir James Dundas-Grant and Dr. Warren Crowe; there is some evidence, Dr. Crowe said, that people with Ménière's disease have a mild degree of water retention, and that they react differently from normal persons on being given water and salyrgan together. The ultimate value of treatment by novasurol and salyrgan was discussed pessimistically by Prof. Fraser, who considered that those patients with heart failure serious enough to merit the treatment were so much wrecked in health as to profit little by the disappearance of œdema. Dr. Bedford, while sympathising to some extent with Dr. Fraser's view, pointed out that the patients themselves place a high value on their increased comfort, even to the extent of attending regularly at the out-patient department for a weekly injection of salyrgan.

[1] Reports on Public Health and Medical Subjects, Ministry of Health, No. 61. 1930. London: H.M. Stationery Office. Pp. 132. 2s. 6d.

POOR-LAW ACCOMMODATION IN BUCKS.—It is officially stated that no accommodation exists in any of the poor-law institutions in Buckinghamshire for cases requiring surgical treatment. Arrangements for the treatment of such cases have, therefore, been made with the Northampton General Hospital, the Royal Bucks Hospital, Aylesbury, and the King Edward VII. Hospital, Windsor. The charge for poor-law in-patients will be 10s. 6d. per day per patient; poor-law out-patients will be treated at a charge of 15s. per head for each course of treatment not exceeding 12 months.

CONSOLIDATION OF PUBLIC HEALTH LEGISLATION.—In pursuance of the policy of consolidating the various statutes regulating the work of the Ministry of Health, a committee has been appointed with the following terms of reference: "With a view to the consolidation of the enactments applying to England and Wales (exclusive of London) and dealing with (*a*) local authorities and local government, and (*b*) matters relating to the public health, to consider under what heads these enactments should be grouped in consolidating legislation, and what amendments of the existing law are desirable for facilitating consolidation and securing simplicity, uniformity, and conciseness." The chairman of the committee is Lord Chelmsford, and its other members: Mr. L. S. Brass, Mr. H. J. Comyns, Capt. Ernest Evans, M.P., Sir William M. Graham-Harrison, K.C., Sir Frederick F. Liddell, K.C., Major J. J. Llewellin, M.P., Mr. E. J. Maude, Major J. Milner, M.P., Mr. Cecil Oakes, LL.M., Sir Harry G. Pritchard, Mr. L. A. J. Granville Ram, Mr. C. E. Staddon, Lieut.-Colonel Sir Seymour Williams, and Mr. R. S. King-Farlow, of the Ministry of Health, as secretary.

CLINICAL INTERPRETATION OF AIDS TO DIAGNOSIS

A Series of Special Articles, contributed by invitation.

LXXXVIII.—BACTERIOLOGICAL EXAMINATION OF WATER.

PART I.*—Objects of the Examination.

THE main object of the bacteriological examination of water is to determine whether it has been subjected to fæcal contamination, and, whether in consequence, there has been distribution to the area of supply of various disease-producing organisms, such as those of enteric fevers (typhoid, paratyphoid), dysentery, and cholera. There is, however, another factor which is of some importance. Bacteria flourish best in water which contains organic impurities, and therefore a bacterial count may give important indications as to the amount of these impurities. If this amount is considerable, the water becomes a more favourable medium for bacterial growth and if, by chance, water in this condition becomes contaminated with fæcal organisms, and particularly with disease-producing ones, their growth will be more active and their multiplication considerable; whereas if the content of the water in organic impurities is low, or, in other words, the bacterial content low, the chances of these disease-producing organisms multiplying will be considerably lessened, and the risk of infection correspondingly lowered. Systematic examination of the water helps considerably in dealing with any defects, and thus keeping the water at what we might call "the minimum point of risk"—i.e., in such a condition that the disease-producing bacteria, if they gain access, have little chance of surviving, or, at any rate, of multiplying.

The available food-supply—i.e., the amount of organic matter—is, therefore, of considerable importance. The more food, the greater the number of organisms in the water. Those which develop at 20° C. —on the gelatin plate—are mostly non-pathogenic to human beings, but they cannot be ignored, for they indicate the amount of food material available for the pathogenic bacteria, and the amount of extraneous matter which has gained access to the water. This bacterial count will be greater during the dusty months of the year and after heavy rainfall, and, in consequence, too much importance must not be attached to it. Temperature, light, acidity, all play a part. But the available food-supply is not the only factor. The effect of temperature varies with the amount of organic matter present. A rise of temperature favours bacterial growth and this is especially the case if the water contains an ample food-supply. On the other hand, when organic matter is small in quantity the rise of temperature actually causes a diminution in the number of organisms. The regular knowledge, therefore, of the total bacterial count of a water-supply is a very important indication to the water engineer or the medical officer, not merely as to the immediate purity of the supply, but as to the capability of the water to deal with a chance contamination with disease-producing organisms. Epidemic disease from a water-supply is, it is true, a rare occurrence, but this does not prove that contamination with disease-producing bacteria is also uncommon. It may be that these organisms occur more commonly than we think, but if the water-supply is a really satisfactory one, then their death or their difficulty in multiplying may save us from an epidemic. For this reason it seems very desirable that we should know quite regularly the capacity of the water to allow the reproduction of bacterial life.

Epidemic disease due to a water-supply is, as has been said, a rare occurrence, but it is very common in any city to find isolated cases of one or other of the forms of enteric fever for which no cause of infection can be traced—cases of paratyphoid fever, &c. Not infrequently these occur over one special area and we look for the cause in the so-called "carriers" or the milk-supply. At other times the condition is more widespread, occurring in widely separated areas. Can we, in all these cases, give a clear verdict that the water-supply is not responsible? It may be objected that if the water was responsible, the outbreak should surely assume almost epidemic proportions. But we should remember that in any properly controlled water-supply these pathogenic organisms would be few and not distributed uniformly through it, and, unless the contamination was very marked, only a few people would be ingesting those bacteria, and of these few perhaps only one would get a sufficient number to set up the disease process.

No system of bacteriological examination can prevent isolated cases of infection, but if there is no systematic and regular examination of the water-supply such a source of infection is not discovered and the isolated cases of infection go on indefinitely.

One instance will suffice for my purpose. In a certain city during the year 1924, 24 cases of paratyphoid fever were notified as compared with three in 1919, five in 1920, two in 1921, three in 1922, three in 1923, and three in 1925—i.e., 19 in six years, and in only three out of these 19 cases was the source of infection not ascertained. The 24 cases were widespread, and the medical officer of health wrote: "The distribution indicates that there was some agency operating in distributing the infection which had not been operative during the preceding years. From investigations made it is extremely improbable that either milk, cream, or ice-cream was the medium of infection. The agent responsible for the spread must be one that is widely used but not heavily infected, and one probably more partaken of by children than by adults." Though an infected water-supply would "fit this bill," yet it would be hazardous to state that the water-supply was the infecting agent. But what are the facts? The cases occurred during the early part of the year, and during the latter part of the previous year the *B. coli* content of the water was high and was continuously so for a period. This called for a special investigation, and during this investigation organisms of *B. paratyphosus* type were isolated and, in some cases, the bacteria gave agglutination reactions with a paratyphoid serum in dilutions up to 1 in 80. The organisms were very few in number, and I think it is, to say the least, probable that they were the causal factor. Now the search for these organisms was wholly dependent on the regular examination and the finding of excessive numbers of *B. coli* continuously over a short period. Eventually these bacteria were traced to their source. Had there been only irregular examinations, this source of infection would have been missed and an increasing number of cases of paratyphoid fever might have occurred, with the possible result of an epidemic of the disease.

TUBERCULOSIS IN MAN AND ANIMALS.

A STUDY IN RESISTANCE.

In communities long civilised and in animals long domesticated a varying degree of resistance or immunity limits and modifies the effects of tuberculosis. We do not, therefore, often get an opportunity in this country of studying natural florid tuberculosis untempered by immunity. "The strengthening against resistance," wrote Sir James Paget[1] many years ago, "the reactions after injury, the turbid activity of repair, the collection and removal of inflammatory products, the casting of sloughs, the discharge of morbid materials from the blood—all these are examples of the manifold good designs of disease; and they evince such strength and width of adaptation to the emergencies of life, we might think the body was designed never to succumb before the due time of its natural decay." And he concludes the matter by remarking that "untimely deaths should make us timely wise." In a monograph,[2] on which we published a short preliminary note last week, Dr. H. H. Scott exemplifies the untimely deaths from tuberculosis of the unprotected. But it is not only the untimely deaths which attract attention to these men and animals, there is also much to be learned from their manner of dying. The florid lesion, the variation in portal of entry, and, quite apart from these portals of entry, the different organs of the body affected in the different natural orders, all combine to make tuberculosis of the non-resistant and unprotected an object lesson in the building up of an immunity. The race is not for the strong but for the immune.

Wild Animals in Captivity.

In the section dealing with tuberculosis in wild animals in captivity (incidentally there are very few data as to tuberculosis in wild animals in their native haunts, but it may be safely assumed that the disease rarely exists, though Cobbett notes three instances in birds) Dr. Scott emphasises a peculiarity of which, at present, there is no adequate explanation—namely, that the organs involved, or most liable to be attacked, appear to differ in different animal species. Furthermore, the tuberculous lesions of captive wild animals differ in two important respects from those met with in the corresponding natural orders of domesticated animals. In the first place, the disease runs a more rapid course; in the second, dissemination of the infecting organism usually takes place early and the lesions are widespread and advanced. It is noteworthy, too, that the wild animal in captivity may remain, to all appearances, in excellent bodily condition up to within a day or two of death from advanced and generalised tuberculosis. The absence of wasting, which is so marked a feature in human beings and domesticated animals, seems to imply a rapid course.

As to the actual incidence of tuberculosis in wild animals in captivity, Dr. Scott believes that the figures at the London Zoological Gardens are probably misleading because fresh batches of animals are constantly arriving (some of which have been in captivity previous to their arrival), and new arrivals, owing to lack of accommodation, may sometimes go straight into cages with older inmates. In more recent days, however, many of the smaller animals have undergone a quarantine period in the sanatorium of the Gardens before being introduced to the society of healthy animals, a provisional isolation which is practised by poultry breeders and others who buy stock from outside sources. As an alternative method of safeguard, in the Zoological Gardens at Philadelphia a preliminary tuberculin test is made. According to Fox, before the tuberculin test was started at Philadelphia the average duration of exhibition life of all monkeys did not exceed 11 months; now it is 35 months. Dr. Scott states that the London Society's record, even without a tuberculin test, has been more fortunate, a considerable number of monkeys live for years without contracting the disease, whilst the proportion dying of tuberculosis has never been a large one.

Localisation in Different Wild Animals.

Turning now to the characteristics of the disease found in different groups of animals, in captive ungulates the well-known serous involvement known as "pearls" is not so common in wild bovidæ as in domesticated. Pulmonary affections of ungulates is a prominent feature, but there are indications, notably in the deer and the buffalo, of pulmonary fibrosis which suggest a certain degree of resistance, and, as in domesticated cattle, calcification may take place early. For some reason, not explained, there is apparent immunity of the spleen. Of the fifteen ungulates with fatal tuberculosis recorded in the series, there is not a single instance of meningeal or intracranial tuberculosis, an immunity recognised in domesticated species also. Taken altogether the facts recorded suggest that the respiratory portal of entry is the common mode of infection in these animals, which is in marked contrast to the disease in monkeys.

Available material for the study of tuberculosis in the latter is much larger, and the reader is referred to a paper by Beattie and Scott[3] dealing with this material, which is republished in the monograph in full. The writers found that the mode of extension of the disease could be explained by the lymphatic distribution, which was worked out with very considerable care and compared with the human cases examined by Dr. Scott in Hong-Kong. Condensing the writers' 10 groups the following classification of the disease in monkeys may be made: (1) cases of undoubted respiratory origin; (2) the same with blood stream dissemination or alimentary infection, or both; (3) cases of primary alimentary infection; and (4) the same with secondary pulmonary infection.

Dr. Scott records 41 instances of tuberculosis in wild birds in captivity in the Zoological Gardens. In these, as in domesticated species, the alimentary tract appeared to be the common portal of entry of the bacillus. Although many orders are represented in the series, including gulls, ostriches, vultures, eagles, and finches, only six examples of respiratory origin were noted and none of these was amongst the gallinæ, the writer's experience supporting that of Fox in Philadelphia that the preponderance of respiratory tubercle occurs only in the Passeres.

[1] Lectures on Surgical Pathology. By Sir James Paget. Second edition. London. 1863.

[2] Tuberculosis in Man and Lower Animals. By H. H. Scott. Special Report Series No. 149. Medical Research Council. HM. Stationery Office. 1930. Pp. 270. 4s.

[3] Jour. Path. and Bact., 1928, xxxi., 49.

As in domesticated birds the type of lesion consisted of isolated nodules having a cretaceous core and giving the impression of being encapsulated, though no capsule is demonstrable microscopically. Pus formation is rare in birds—possibly, as Dr. Scott suggests, because the polymorphonuclear leucocyte is present in much smaller numbers—and, instead of breaking down and softening, a dry necrosis results. Tuberculoma, gelatinous tuberculosis, and three types of intestinal tuberculosis are found, whilst tuberculosis of the liver and spleen are common.

Comparing these records of tuberculosis in captive wild animals with those of domesticated animals and with man, one is struck by the fact that bone and joint tuberculosis and tuberculosis of the central nervous system, which play a considerable part in the tuberculosis mortality in man, are extremely rare in animals both domesticated and wild. These two types are almost unknown, too, in laboratory animals. As far as we know, no adequate explanation is forthcoming on the point and the experimental work thereon is meagre. Excepting the bovines, rabbit, guinea-pig, and rat, which have been extensively used for experimental purposes, the histological side of animal tuberculosis has not been exhaustively explored. When this work is done many of the gaps in our knowledge of the comparative pathology of tuberculosis will doubtless be filled up, and it is possible that an explanation of the rarity of lesions of bones and joints and of the central nervous system will be forthcoming.

Domesticated Animals.

On the question of tuberculosis in domesticated animals, there is, of course, much more information available. The disease is common amongst bovidæ, and has been so well worked out by the Royal Commission that nothing further needs to be said here. Tuberculosis in the dog was at one time considered very rare, perhaps partly because the lesions are often confused with those of sarcoma. Cobbett [4] some years ago compiled a table of published records from the veterinary schools of Europe which varied from 0·06 per cent. in Berlin to 5·6 in Paris. Dr. Scott has now collected the histories of 100 cases. The infecting bacillus was human or bovine, but the former predominated. Of these animals 51 lived in restaurants or cafés where the floors were constantly soiled with human expectoration, and 23 others were in intimate contact with sick persons. Dogs frequenting abattoirs may also become infected. Tuberculosis of the lungs and pleuræ are common, and unlike tuberculosis in man, in whom it is of extra rarity, the pericardium is, according to Cobbett, not an uncommon site of infection.

In domestic birds Dr. Scott states that tuberculosis is fairly common. It is found in gallinaceous birds, in parrots, and in canaries. The disease is a frequent occurrence in gallinæ, and it is met with in epizoötics. It has, indeed, been fairly well worked out. Infection spreads by the excreta, emaciation is marked, and the indications of an alimentary root of infection far exceed the respiratory, the liver and spleen swarming with bacilli. Parrots and canaries are stated to be susceptible to the mammalian types of the tubercle bacillus as well as the avian, and infection from man is on record.

Post-mortem Experience in Hong-Kong.

The findings in the 300 cases of tuberculosis in the human being examined post-mortem in Hong-Kong occupy a considerable part of the monograph. There were 225 children under 10 years of age in the series. Although tuberculous mediastinal glands generally indicated a lung lesion there were 13 per cent. of cases of caseous tracheo-bronchial glands without any focus in the lung, and in rather less than half of these there was evidence in favour of an alimentary portal of entry. For the rest the evidence appeared to be generally in favour of a respiratory origin. In only one instance amongst the children recorded in the series was there an old healed shut-off focus present. This was in a child aged 3 in which the middle lobe of the right lung showed an old fibrous and calcareous nodule, with a terminal generalisation of the disease in the lung and tuberculoma of brain. Meningeal tuberculosis was fairly common as a terminal blood infection. Instances of involvement of the urinary tract, except as part of a generalised vascular dissemination, were rare. There were two rare cases in which there was a tuberculous infection of the internal genitalia in female children of 8 months and 4 years of age respectively. But perhaps the most interesting of all was a group of five infants, three aged respectively 22, 24, and 29 days, and two aged 7 weeks. In the first three there was no disease other than miliary or broncho-pneumonic lesions of the lungs, even the lymph glands being unaffected. In the two of 7 weeks the disease had advanced to the mediastinal glands and pleura, and one had a small cavity in the lung. This series in such young infants, even though of an unprotected race, must be almost unique. They were evidently primary respiratory infections, and presumably resulting from massive doses. Indeed, throughout the series of the Hong-Kong cases the reader is impressed with the intensity of the infection. The natural assumption is, of course, that such acute cases, as in the case of the wild animals in captivity, exhibit tuberculosis in a virgin soil untrammelled by immunity and resistance. But there is another side of the question on which we are still woefully ignorant—viz., the size of the infecting dose. It requires no stretch of imagination to realise that a people coming into contact with Western civilisation may adopt the ways of life of the West in its manifold activities without adopting the standards of cleanliness and natural safeguards of health which the Westerner uses almost as a reflex action. And when lack of immunity and absence of safeguards go hand in hand the result is a foregone conclusion.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

THE WHITE HOUSE CONFERENCE.

THE culmination of more than a year's work of facts, findings, and discussion by more than a thousand experts in the fields of child health and education has been reached in the White House Conference, which met in Washington, D.C., from Nov. 19th to 23rd. The conference was augumented to 3000 members by delegates who were invited by President Hoover to attend. Reports of committees were already available in print, and usually these reports have been endorsed by the conference itself. In many cases the conclusions are already well established in child welfare practice and no debate could be expected. In these cases the purpose of the conference seemed to be rather one of popular education than of creative imagination on scientific research. In certain sections—notably the section on medical

service—so much material had been collected that it was found impossible to digest it in time for the conference. The work of this section will, therefore, be continued into next year.

In only one instance did a serious dispute arise over the work of the preliminary committees. The subcommittee of the section dealing with reorganisation of the federal health service recommended that the maternity and infancy work be taken from the Labour Department (Children's Bureau, under Miss Grace Abbott), and transferred to the public health service. Miss Abbott, herself a member of this subcommittee, wrote a minority report in which she said that "the conception of the unity of the child and the value of having the discipline and techniques of the social, medical, statistical, and other related sciences associated in the scientific study was advocated by the conference of 1909 and enthusiastically approved by President Roosevelt and, in turn, by Congress . . . . There is ample evidence that this plan of unified approach has greatly increased public interest in all the problems of children and child life. To remove the health work from the Children's Bureau would not merely remove one section of the Bureau's activities; it would destroy it as a Children's Bureau."

This minority report, in the haste of assembling material for the conference, was omitted from the printed volume of preliminary committee reports. But the omission came to the attention of representatives of women's organisations in the conference, and overnight a remarkably strong protest movement against the majority recommendation made itself manifest. The attempt of the majority of the committee to ignore this protest movement and even to prevent it from becoming vocal merely added to its momentum. It was an astonishing spectacle to see the surgeon-general of the public health service rebuking a leading sociologist for introducing remarks on social welfare in a section on public health matters, and one which gave some force to Miss Abbott's previous arguments. Good sense ultimately prevailed, and the disputed recommendation was referred to a continuation committee, which was instructed to bring in a unanimous report. The conclusion of this same subcommittee that "the creation of a new department with a cabinet officer for the direction of federal health activities is not essential at present to the accomplishment of the objectives to be proposed" passed the conference without exciting any comment. Nor was there any overt criticism of the recommendation that federal grants in aid of health be continued and increased. If the American Medical Association was represented its representatives raised no voice of protest against this continuation of the functions of the late Shephard-Towner Act. It is possible that the excitement over the work of the Children's Bureau prevented discussion upon these other important matters.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

NEW REMEDIES AND OPERATIONS.

IN a recent address to the Pharmaceutical Society in Edinburgh Dr. Ralph Stockman, professor in materia medica and therapeutics in the University of Glasgow, dealt with some very practical points. He said it had to be admitted that the profession owed the introduction of some good remedies to manufacturing chemists, and these deserved gratitude also for furnishing reliable preparations of proved and attested remedies mostly in a convenient and pleasant form. There their legitimate function ceased and the rôle of teacher of pharmacology and therapeutics did not appertain to them. Infant foods and artificial foods generally had a dubious record from the point of view of therapeutic activities. The same might be said of treatment by serums and vaccines and also the development of endocrinology, which had furnished medicine with invaluable remedies. A weakness in the medical curriculum was the very large amount of mere description on the teaching side and an almost equal amount of mere memorising on the student side, with a minimum of those disciplines, such as mathematics or physics, which tend to develop reasoning power. This was inherent in biological studies and possibly unavoidable in medicine, but possibly not. It was essential to ensure that during studentship some actual experience in treatment was available. It had sometimes crossed his mind that therapeutic practice might be stabilised intra-professionally by imitating the procedure of their legal confrères and establishing a medical court with medical judges, solicitors, advocates, and juries. Before these courts, with their experienced personnel, highly trained in weighing the law of evidence, new drugs, new treatments, and new operations might be summoned to appear and show reasons for their existence and practice. Some such filter or buffer would be of incalculable benefit to the medical profession and a protection to the public at large.

ALCOHOL AND THE LAW.

In his Henderson lecture on Alcohol and Behaviour Prof. Sydney Smith said that under the new Road Act it was an offence to drive a car while "under the influence of alcohol, to such an extent as to be incapable of proper control of such vehicle." We knew, he said, that any quantity of alcohol diminished the control, and as this loss was gradually progressive, it was impossible to fix any exact point at which a person became incapable of driving a car. The question of diagnosis was thus going to be very difficult. Even when we knew the amount that a person had drunk we were not much further forward, for the effect of drink was not only different in different individuals, but varied enormously in the same individual at different times.

Prof. Sydney Smith also emphasised the fall in the consumption of alcohol in Great Britain. The annual consumption of beer had, he said, diminished to half, and the consumption of whisky to about a quarter, of the amount used in 1900. In the present year this fall was continuing. With this fall in alcohol consumption there had been a similar diminution in arrests for drunkenness, from about 200,000 in 1900 to 60,000 in 1928. The lecturer pointed out that although drunkenness had progressively diminished, sexual crimes had progressively increased. Thus, in the period 1900–04 there were about 1400 cases of rape and other sexual crimes annually, whereas in 1929 there were over 3000 similar cases. There seemed to be little correlation between drunkenness and the more serious crimes of violence and sexual crimes, but it bore a close relation to minor violence, neglect of children, and similar offences. Moderate indulgence in alcohol did not appear statistically to prejudice the expectation of life, but this finding should be accepted with some reserve.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

SWEEPSTAKES AND AFTER.

THE present legislation governing the promotion of sweepstakes in the Irish Free State limits their benefits to such hospital charities as fulfil certain statutory conditions. The success of the recent sweepstake on the November Handicap has suggested to some that these limitations should be abolished, or made less stringent, so that a different class of institutions might benefit. A Bill was introduced to the Dáil last week for the purpose of permitting rate-supported hospitals to share in future sweepstakes. The fate of the Bill is as yet uncertain, but it is clear that what it proposes is something much more than merely the extension of the application of sweepstakes. It introduces a new principle. If the ratepayers are to be allowed to relieve themselves of their financial responsibilities in regard to the maintenance of institutions for the sick, there seems to be no reason why they should not throw their other burdens on the gambling public also. Why not have lotteries for the upkeep of roads, the building of bridges, the provision of houses, and the thousand other activities for which the rating authorities are responsible? If the ratepayer is to be relieved in this way, why not the taxpayer? The way is open for the return of State lotteries.

Meantime, while those who have received sums beyond their hopes for the charities in which they are interested are intoxicated with their past success and their hope of future, there is a growing feeling of distrust of the sweepstakes as a method of financing hospitals, and this feeling is by no means confined to, though most strongly expressed by, the professional moralists. The latter, it is true, had their innings last Sunday, on the occasion of the annual collection in many of the Protestant churches on behalf of the Dublin Hospital Sunday Fund. The benefits of the Fund are to be confined to the hospitals which do not share in the profits of sweepstakes. The clergy, in nearly all cases, made a strong appeal on behalf of these deserving and self-denying charities, and at the same time gave their reasons for opposition to sweepstakes. In so far as these are based on moral grounds the matter is not one for discussion here, but the Archbishop of Dublin and some other preachers touched on another point of great importance on another plane. The Archbishop suggested that to harness the sacred name of charity to appeals to personal gain might strike a serious blow at the voluntary system of giving. Many go further, and are inclined to think that a few more successful sweepstakes are not unlikely to strike at the very foundations of our voluntary hospital system. This may be good, or it may be bad, but it is very far from what was intended by the original promoters of the legislation permitting sweepstakes. If hospitals can derive adequate support from sweepstakes or lotteries, the stimulus to voluntary support is gone. In time, indeed, the support of the hospitals may become a mere incidental tax paid by professional promoters for the privilege of running a sweepstake. It is to be noted that the fees paid to the professional promoters in the recent sweepstake were little less than one-third of the sums paid to the hospitals. The problems raised by a successful sweepstake are much greater and more far-reaching than were at first recognised.

GENERAL MEDICAL COUNCIL.

Committee Business.

(*Concluded from p. 1258.*)

DIPLOMAS OF PUBLIC HEALTH: REVISED RULES.

Sir John Moore moved the adoption of the report of the Public Health Committee, and with it the revised rules governing diplomas and degrees in public health, sanitary science, and State medicine.

Sir George Newman, the chairman of the sub-committee responsible for the revised rules, explained that three reasons had led to the revision. The first was the rapid development of the practice of public health, particularly in obedience to many statutes passed since the framing of the old rules in 1921. The public health officer had become more clinical and less analytical. Moreover, the new medical curriculum had considerably altered the capacity of the men presenting themselves for a diploma. The second reason was the difficulty which the schools, especially the new London School of Tropical Medicine and Hygiene, had found in conforming to the old rigid requirement that the course should occupy 12 calendar months. The third reason was the passing of the Local Government Act, 1929, which had greatly increased the clinical responsibilities of public health officers.

The Council, when directing the revision, had expressed its desire, said Sir George, to reduce the number of candidates who did not intend to practise public health work. Rule 1 had been left substantially alone, but the note appended to it now referred to the clinical aspects of State medicine.

Rule 1.—A period of not less than two years shall elapse between the attainment by a candidate of a registrable qualification in Medicine, Surgery, and Midwifery and his admission to the Final Examination for a Diploma or Degree in Sanitary Science, Public Health, or State medicine.

The purpose of Rule 1 is to provide opportunity for candidates, while passing from the state of pupilage to that of responsible practice, to give mature consideration to the obligations and duties involved in the work of the Public Health Service, and to acquire direct experience of medical work in a responsible capacity, in general medical practice, in hospital or laboratory appointments, or in any special branch of clinical work or study related to State medicine. The Council believe that, in the public interest, the time has arrived to adapt the Diploma or Degree to candidates who are seriously intending to take up Public Health work as a career.

Rule 2 contained the cardinal alteration affecting the arrangements of the schools.

Rule 2.—The curriculum for a Diploma or Degree in Sanitary Science, Public Health, or State medicine shall extend over a period of not less than twelve calendar months (or an academic year of whole-time study covering a period of not less than nine calendar months) subsequent to the attainment of a registrable qualification.

Rules 3 and 4 no longer prescribed a definite number of hours for each of the special subjects, but left the distribution of the aggregate time to the discretion of the teaching bodies.

Rule 3.—Every candidate shall produce evidence of having attended, during not less than 280 hours, at an institution approved by the Licensing Body granting the Diploma or Degree, practical instruction in: (*a*) Bacteriology and Parasitology (including immunology, serology, medical entomology, &c.), especially in their relation to diseases of man, and to those diseases of the lower animals which are transmissible to man; (*b*) Chemistry, Physics, Radiology and Electrology in relation to Public Health; (*c*) Physiology and Biochemistry in their application to nutrition and hygiene; (*d*) Meteorology and Climatology in relation to Public Health.

Rule 4.—Every candidate shall produce evidence of having received, during not less than 120 hours, at an institution

approved by the Licensing Body granting the Diploma or Degree, instruction in the following subjects: (*a*) The Principles of Public Health and Sanitation; (*b*) Epidemiology and Vital Statistics; (*c*) Sanitary Law and Administration (including Public Medical Services); (*d*) Sanitary Construction and Planning.

The subcommittee, continued Sir George, had added to Rule 3 (*a*) immunology and serology, and to (*b*) radiology and electrology; (*c*) introduced something in the nature of a new subject, in response to the unanimous demand of the schools. The total of hours allotted to the subjects in Rule 4 was slightly increased.

Rule 5 required the daily attendances at a recognised hospital for infectious diseases to number 24 instead of the awkward figure of 30.

Rule 6 laid down that instruction in the administration of the special services should include attendance at the centres or institutions concerned. Rule 7 had not been changed and Rules 8 and 9 had been shortened.

Rule 8.—The examination for Part I. shall be practical, written and oral, and shall include the subject referred to in Rule 3.

Candidates may not be admitted to examination for Part I. until after they have completed the prescribed courses of instruction in the subjects thereof.

Rule 9.—The examination for Part II. shall include the subjects referred to in Rules 4, 5, and 6. The examination shall be written and oral, and shall include practical examinations in Infectious Diseases; Food Inspection; Inspection of premises—dwellings, factories, workshops, schools, &c. Candidates may not be admitted to examinations for Part II. until after they have completed the prescribed courses of instruction in the subjects thereof. No candidate shall be admitted to Part II. of the examination for a registrable Diploma or Degree in Public Health until after the lapse of not less than two years from the date of his obtaining a registrable qualification in Medicine, Surgery, and Midwifery, which qualification must be registered in the Medical Register before admission to Part II. of the examination.

Sir Robert Bolam proposed to amend Rule 1 to read: "Not less than two years shall elapse between the registration (instead of 'the attainment') by a candidate of a registrable qualification" in medicine. He considered that this alteration was necessary to ensure that candidates had sufficient experience of the practice of medicine, and to prevent them from entering if they had sequestered themselves in laboratories or scientific work. Sir George Newman expressed his sympathy with the principle, but considered that the amendment would involve excessive hardship, especially—as the President emphasised—to candidates from overseas, and the Council rejected the amendment.

THE NEW SPECIAL SUBJECTS.

The additions to the special subjects excited a lively debate. In reply to questions from Dr. Jamieson and Mr. Eason, Sir George said that, as medical officers of health would now exercise supervision over a large number of institutions in which electrical apparatus was used, it was necessary that its clinical application should not be foreign to them, and that they should be able to advise on its installation and employment. Mr. Monsarrat and Sir Robert Bolam objected that it was impossible in the time to give a candidate a sufficient equipment to enable him to advise on the installation of or treatment by electrotherapeutic apparatus, and Sir Robert moved the deletion of the words "radiology and electrology." Dr. Sheen, in seconding the motion, suggested that logically every specialty should be included in the course, which was in danger of becoming as badly overloaded as the general curriculum. Sir George Newman retorted that it would be better to omit chemistry and physics. It was not, he said, intended to make any candidate a specialist, but to enable him to give intelligent advice to his authority.

Sir Robert Bolam's amendment was lost by 11 votes to 16, but Sir Holburt Waring proposed and Sir Norman Walker seconded an amendment to insert the words "and Biophysics." Mr. Monsarrat objected to the introduction of further complications into a course which already required the services of several teachers, and this amendment was also rejected. Nothing daunted, Dr. Brackenbury proposed to add to the syllabus a course of genetics, but withdrew his motion on learning that it was open to any licensing body to include this subject in the syllabus.

The revised rules were adopted. The words "Medical Register" were substituted by the Council at the end of Rule 9 for the words "Great Britain."

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 29TH, 1930.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 160 (last week 116); scarlet fever, 2182; diphtheria, 1526; enteric fever, 36; pneumonia, 1016; puerperal fever, 36; puerperal pyrexia, 118; cerebro-spinal fever, 16; acute poliomyelitis, 12; acute polioencephalitis, 1; encephalitis lethargica, 12; dysentery, 10; ophthalmia neonatorum, 107. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Dec. 2nd–3rd was as follows:—Small-pox, 236 under treatment, 2 under observation (last week 221 and 3 respectively); scarlet fever, 1944; diphtheria, 2217; enteric fever, 14; measles, 84; whooping-cough, 106; puerperal fever, 23 (plus 10 babies), encephalitis lethargica, 121; poliomyelitis, 2; "other diseases," 47. At St. Margaret's Hospital there were 15 babies (plus 5 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 33 (0) from measles, 1 (0) from scarlet fever, 5 (1) from whooping-cough, 44 (9) from diphtheria, 44 (11) from diarrhœa and enteritis under two years, and 56 (5) from influenza.

The fatal case of enteric fever was reported from Barnsley. Nine fatal cases of measles occurred at Hull, 6 each at Bristol and Liverpool. Nine deaths from diphtheria were reported from Liverpool. Diarrhœa accounted for 7 deaths at Liverpool, 3 each at Nottingham and Salford. Influenza was credited with 5 deaths at Liverpool and at Manchester, 4 at Salford, and 3 at Bolton.

The number of stillbirths notified during the week was 273 (corresponding to a rate of 44 per 1000 births), including 59 in London.

CHRISTIE CANCER HOSPITAL.—This Manchester Hospital is to be rebuilt, and it is hoped to begin the work shortly. The British Empire Cancer Campaign has contributed £25,000 and a similar amount has been received from legacies; patients and their friends have given £800. A further large sum will, however, be needed. It is hoped to have the hospital completed by the end of 1932.

LONDON HOSPITAL MEDICAL SCHOOL.—At present this school, the finances of which are entirely distinct from those of the hospital, rents three neighbouring houses which accommodate, not very satisfactorily, 22 students. The need for better quarters is so great that the medical and surgical staff have started a fund, now amounting to over £2000, to which they have themselves subscribed liberally. It is hoped to raise sufficient money to build a hostel close to the hospital which, in Lord Knutsford's words, "would not merely give board and lodging, but would provide some of the features of the collegiate life of the Universities."

PUBLIC HEALTH SERVICES

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1929 statistics of two counties and the island of Guernsey :—

Name of city and estimated (R.-G.) mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality from childbirth.
Derbyshire .. (624,300)	16·6	11·6	0·71	1·15	2·4	1·9	68/—	—	3·7
Rutland .. (18,100)	14·4	14·3	0·72	1·50	3·3	2·4	84/—	—	3·8
Guernsey .. (39,040)	19·4	15·1*	0·90	1·82	2·5	1·8	79/44	20	0·0

Registered stillbirths per 100 live births: Derbyshire 5·0. Rutland —, Guernsey 4·4.
* Standardised 12·0.

Derbyshire.

Dr. W. M. Ash cites as an example of the need for coöperation and coördination of voluntary and official bodies that one of the nine committees of the council, which deal with medical services, is at present considering subscriptions to 100 voluntary organisations for the treatment of the sick. He goes on to discuss hospital accommodation of all types. For isolation accommodation existing hospitals should serve larger areas. Some new hospitals will be required and reciprocal arrangements can be made with the hospitals of county boroughs. Isolation hospitals can serve large areas by means of motor transport because they need not be so readily accessible for visitors and the staffs, and patients for these larger (and therefore more economical) hospitals should be interchangeable. As regards general hospitals, Dr. Ash shows that there is at present a nucleus institution within easy reach of any district in the county, and such nucleus institutions he would have developed into comprehensive hospitals, which would receive medical, surgical, obstetrical, and gynæcological cases from a given area, and comprise children's wards and, if necessary, accommodate the school clinic, maternity, and child welfare centre and tuberculosis dispensary. Each area hospital would thus become a centre of both preventive and curative medicine. Convalescent homes are also needed and accommodation for long-stay cases other than surgical tuberculosis. Dr. Ash also strongly urges that all incipient and early cases of mental sickness should be kept quite apart from the confirmed and advanced cases. He would have the large general and especially the teaching hospitals provide both in-patient and out-patient treatment for this type of case, for if prevention is going to be successfully applied in mental infirmity, early mental treatment must be taught to every medical student. The county antenatal scheme is now functioning fully, and the 12 clinics conducted by Miss E. E. Stephens, M.D., were attended by 939 antenatal cases and 215 postnatal.

The notifications of diphtheria were 649 and the deaths 45—a case-fatality of 6·9 per cent. There were 26 cases of enteric fever with 6 deaths. Two cases occurring, one in March and one in October, in different areas illustrated the difficulties of the carrier problem. Investigation showed that a Mrs. X was living at each house when the case occurred. During 1927 and 1928 two other cases had occurred in houses where she stayed. Three consecutive and several single examinations of fæces and examinations of the urine, also Widal and agglutination tests, all proved negative. Finally, of four consecutive fæcal examinations the first three were negative and the fourth gave a subculture of *Bacillus typhosus;* the fifth and sixth were negative, and the seventh positive. Mrs. X was much distressed and agreed to have her gall-bladder removed. The bile in the gall-bladder gave abundant growth of *Bacillus typhosus* in pure culture, even in dilution of 1 in 1,000,000.

The efficient arrangements made for consultants and admission to hospital is making the notification of puerperal fever more effective, but Dr. Ash points out that, where a case obviously requires hospital treatment, the expense of calling in a consultant as well is unnecessary. All the midwives in the county have been urged to wear masks while attending confinements, especially if suffering from a cold or throat infection.

The orthopædic scheme has been extended. The eight beds at Bretby Hall for non-tuberculous cases have been increased to 65. An additional clinic has been opened at Heanor and considerable progress made with the new 32-bed block for adults suffering from surgical tuberculosis. An endeavour is being made to provide more accommodation for advanced pulmonary tuberculosis within easy reach of the relatives. The sandstone industry (silicosis) scheme came into force on April 1st and 18 new employees were examined by the tuberculosis officers. Under the Housing (Rural Workers) Act, 1926, only nine applications for grants had been received up to the end of 1929. One application was withdrawn and another refused, and grants to the extent of £475 were made in respect of seven dwellings. The classification of the 623 samples of sewage effluents collected during the year was as follows: good, 211; satisfactory, 164; unsatisfactory, 103; and bad, 145.

Dr. A. N. Robertson, medical superintendent of Walton Sanatorium, is not impressed with the value of gold therapy after trying allochrysine and collosol gold. He never saw any harm result from tuberculin if used with proper care, but thinks it occasionally did good, and has a hankering after its use again. He has no doubt of the immense value of surgical methods in suitable cases. Of all diagnostic tests he still places most reliance on the subcutaneous tuberculin method. The number of patients admitted was 343. Ten new cases began artificial pneumothorax treatment and 19 old cases continued. Red ray treatment by the Murray Levick lamp in cases of pleural effusion has been found useful in diminishing the number of gas replacements.

Rutland.

Dr. Christopher Rolleston reports that his council has made one "declaration" under the Local Government Act, 1929, and that in regard to tuberculosis. The functions of the public assistance committee with regard to poor children apart from their parents and mental defectives will be discharged by the education and mental deficiency committees respectively. The remaining services for mothers and children will be discharged by the maternity and child welfare committee. Dr. Rolleston rejoices at the decline of the birth-rate, partly because of the future of the world's supply of food and partly because men are being replaced by machines. The latter reason does not seem cogent, seeing that the work of the world varies according to its population. The proper solution would seem to be reduction of the hours of work for all! The deaths were greater than in any year since 1918. Dr. Rolleston recommends the provision of trained nurses for the home treatment of pneumonia and arrangements for hospital treatment if the home is unsuitable. The births numbered 261 and 63 maternity outfits were supplied by the council. There were 38 attendances at the orthopædic clinic

at Peterborough, 14 of which were for rickets and 15 for infantile paralysis. Apparatus was provided in 12 cases and six children were admitted to Manfield Hospital. In August-September there was an outbreak of six cases of poliomyelitis at Morcott (population 384). The first cases were not diagnosed. One case, a girl of 13, died. In two cases, aged 8 and 15, the paralysis was confined to the facial muscles. The other three cases, all of the pre-school age, are receiving special orthopædic treatment. The ascertainment and care of the mentally defective and blind is being carried out thoroughly. Several very satisfactory renovations have been made under the Housing (R.W.) Act, and Dr. Rolleston would like to see this Act more used. A modern cement factory has been established at Ketton and employs 140 men. Dr. Rolleston, who lives near the works, is able to say that the amenities of the village have not suffered.

Guernsey.

Dr. H. Draper Bishop reports that the island did not escape the influenza epidemic, which was very fatal to old people. He draws attention to the fact that neither he nor the sanitary inspector has a right of entry to premises, except when infectious disease is notified. Each of the ten parishes has a constable as its executive officer and with the exception of the town parish the constable seldom desires assistance from the States' officials. Dr. Bishop hopes the States will, this year, grant their officials the same right of entry as is given in England. It is difficult to secure support for nursing and infant welfare associations, which are limited to three of the parishes at present. In Jersey there is a nurse for every parish, and Dr. Bishop would like to see a similar arrangement in Guernsey. About one-seventh of the births take place in the Lady Ozanne Maternity Home. A special committee has provided houses for 263 families since 1918, but there is still much overcrowding and a shortage of small houses. The crematorium at the States' Cemetery was completed during the year, and should have a special application owing to the limited area of land available. Dr. Bishop is not school medical officer, but he examined during the year 420 children sent to him by the school nurse.

The chief industries of the island are growing fruit, vegetables, and flowers under glass, granite quarrying, and the rearing of cattle. The latter are said to be free from tuberculosis, so that a special interest attaches to the deaths from non-pulmonary tuberculosis. There were six such deaths (a rate of 0·16) in 1929—namely, two at age-period 5 to 15, tuberculous peritonitis and tuberculous meningitis respectively; two at age-period 15–25, tuberculosis of joints and spine respectively; and two at age-period 25 to 65 from tuberculosis of kidney and spine respectively.

MENTAL HOSPITAL REPORTS.

Of the WEST RIDING MENTAL HOSPITALS that at WAKEFIELD had 2395 patients in the institution at the end of last year. The recovery-rate was 25·9 per cent. and the death-rate 7·5 per cent., the lowest on record for this institution. Autopsies were performed in 88·7 per cent. of cases. The institution shop has proved a very great success. The laboratory performed over 4000 examinations during the year and the operating theatre and the X ray and light department were kept busy. There was no typhoid, but 11 cases of dysentery. The out-patient department received 65 new cases, bringing the total on the register to 180. A great deal of work has been carried out in an attempt to bring this old institution into line with modern requirements. Parole has been given to 38 men and parole within the estate to 120 men and 497 women. There are a number of young people in the hospital, and troops of boy scouts, girl guides, and wolf cubs are run for them; they attend handicraft classes and keep pets. Fifty-four women nurses work on the male side; two nurses obtained their G.N.C. certificate during the year, bringing the total of certificated or registered to 85 men and 24 women. The hospital at STORTHES HALL, KIRKBURTON, near HUDDERSFIELD, had 1771 patients in residence on Dec. 31st last. The recovery-rate was 28 per cent. and the death-rate 8 per cent. Money allowances were granted to 24 discharged patients. Owing to an increase of 60 beds provided during the year, the hospital has now room for 1836 patients and is therefore not overcrowded. The general health during the year was good; there was no typhoid and only six cases of tuberculosis. There were 14 cases of dysentery, 11 of erysipelas, and some influenza. Useful work was provided for 50 per cent. of the men and 40 per cent. of the women. A variety of occupations are available, and the numbers are satisfactory considering the large number of senile and chronic patients. During the year a class in mat-, basket-, and rug-making was started for the blind. Malarial therapy was continued for general paralysis in 14 cases; one patient left to resume his work and six improved. A welcome addition to the hospital equipment is the new treatment centre, containing an operating theatre and sterilising room, and X ray, actinotherapy and dental rooms. The dentist attended weekly and saw a large number of patients. The laboratory performed nearly 4000 examinations. Two shops were opened where patients can buy necessities; any profits will be directed to the provision of amusements. During the year ten attendants and five nurses passed the final R.M.P.A. examination and one nurse the final G.N.C. examination. There are now 52 attendants and 32 nurses certificated or registered.

Of the two HAMPSHIRE MENTAL HOSPITALS, that at KNOWLE had 1056 patients on its books on the last day of last year. The recovery-rate was 32·78 per cent. and the death-rate 5·6 per cent. The cause of death was verified by post-mortem examination in 71 per cent. of the fatal cases. There were five cases of typhoid, and a search for carriers is still being made. There was one case each of scarlet fever, diphtheria, and measles. Six cases of general paralysis were treated by malaria and two were discharged recovered. A new admission block and a new nurses' home are under consideration. During the year six nurses obtained their R.M.P.A. certificate. At PARK PREWETT there were 1298 patients at the end of 1929. The recovery-rate was 22 per cent. and the death-rate 8 per cent. There were only five cases of tuberculosis under treatment at the end of the year. Four deaths resulted from this disease, three from dysentery, and five from influenza, but the general health was good. A series of sporadic cases of erysipelas has now ceased. The consulting surgeon performed four major operations and the dental surgeon and ophthalmic surgeon attended regularly. Two cases of general paralysis treated with tryparsamide were discharged recovered, but other cases showed little improvement; three men were sent to Knowle for malarial treatment. The pathological laboratory, in addition to routine investigations, has been studying undulant fever, three cases of which appeared in the hospital. The Meinicke micro-reaction is used as a routine test for all new cases. A new nurses' home was opened during the year and eight cottages for married staff have been built. Ultra-violet ray apparatus has been installed in the admission hospital and a villa has been equipped for male patients on parole. Every effort is made to induce patients to work, but the visiting commissioners urge the appointment of an occupations officer. Eight nurses passed the R.M.P.A. examination.

"PENNY-IN-THE-POUND NEWS."—This new organ of the Merseyside Hospitals Council, issued free, describes each month the progress of the remarkably successful contributory scheme. In the November issue Mr. Sydney Lamb, the secretary of the council, tells how the scheme came into being, and describes the rapidity of its progress, but estimates that there are still some 225,000 persons who ought to be enrolled. At least 95 per cent. of the large firms have, however, already joined the scheme. By means of an ingenious pictorial map an appeal is made to motorists to volunteer to take relations of patients to hospitals in urgent cases during the night.

CORRESPONDENCE

PASTEURISATION OF MILK.

To the Editor of THE LANCET.

SIR,—In view of the importance of milk in the diet of both children and adults, it is necessary for the known facts regarding the safety of this article of food to be placed before consumers and all concerned.

It is widely acknowledged that the average consumption of milk in this country could be greatly increased to the benefit of the public health and the improvement of the national physique. A substantial increase, however, cannot be anticipated until public opinion demands the highest standards and practice of milk production and distribution.

In this country an effort has been made to improve the milk-supply by means of a grading system and, notwithstanding a certain measure of confusion that has arisen from the excessive number of grades, it is still fundamentally true that the ideal milk supply would be that which would conform to the highest grade defined by the Ministry of Health, namely, "Certified milk."

In practice, however, it is found that only a very small proportion of the public are able to afford this grade, even for the feeding of infants, and the same position, in varying degrees, applies to the other grades that lie between it and pasteurised milk, which is the form of milk commonly distributed in great centres of population. Experience has shown that where pasteurisation (the heating of milk under conditions which ensure the destruction of harmful bacteria, yet leave the vitamins unimpaired) is generally practised, infection traceable to milk recedes almost to vanishing point. This fact has led no fewer than 21 cities in the U.S.A. to ordain the compulsory pasteurisation of milk.

The signatories, while expressing no opinion on the principle of compulsion, are emphatically agreed that the time has arrived when, in order to increase milk consumption and diminish the risk of milk infection, pasteurisation should be universally recognised as the immediate practical method of ensuring safety. They record their satisfaction at the fact that about 90 per cent. of the London supply is pasteurised with markedly beneficial results.

They are of opinion that the first step in educating the public to demand pasteurised milk should be the simplification of the present milk grading system and the clear labelling of pasteurised milk as such. They are further of opinion that while no effort should be relaxed to improve milk at the source, the entire milk-supply—excepting "Certified milk"—should be pasteurised.

We are, Sir, yours faithfully,

NEUTRALISATION OF POLIOMYELITIS VIRUS.

To the Editor of THE LANCET.

SIR,—In an article published in your issue of Oct. 25th (p. 895) Dr. R. W. Fairbrother and Dr. W. G. Scott Brown record the results of experiments on the action of the serum of various individuals on the virus of poliomyelitis. They conclude that immunity to the poliomyelitic virus, as indicated by the presence of antivirus, is frequently present in normal people who have been in contact with definite cases of the disease without developing it. They quote the work of Anderson and Frost (1911) who, in seven normal individuals (employed as controls in investigating the serum of cases of poliomyelitis), found complete neutralisation in one case and partial neutralisation in two cases.

Will you permit me to draw attention to my researches [1] in collaboration with C. Kling on the Swedish epidemic in 1912. We studied the serum of nine normal individuals, of whom seven were close contacts with cases of poliomyelitis and two, children of 14 months and 2 years of age respectively, had never suffered from poliomyelitis or been in contact with cases. In the first series there was complete neutralisation in two cases, partial neutralisation (lengthened incubation period in the monkeys inoculated) in four cases, and no neutralisation in one case. In the second series there was almost complete neutralisation (incubation period of 32 days) in one case and no neutralisation in the other. Thus the serum of certain healthy individuals, most of whom were living in an infected area and—so far as could be judged from clinical manifestations—showed an immunity to the virus, neutralised completely the virus of poliomyelitis in the proportion of almost a third, and partially in the proportion of 5 : 9. We concluded that microbicidal properties which totally or partially neutralise the virus of infantile paralysis are present in the serum of individuals who have been living in intimate contact with cases of poliomyelitis without developing the disease. Their immunity could therefore be attributed to the presence of these microbicidal substances in the blood. We also stated our opinion that the immunity was due to latent infections, the organism reacting to the virus only by the production of antibodies, or, in some instances the immunity followed the abortive form of the disease that had not been diagnosed as such.

These results explain the unequal receptivity of human subjects to the virus of poliomyelitis during the course of epidemics.

I am, Sir, yours faithfully,

Dr. C. LEVADITI,
Paris, Dec. 2nd, 1930. Professeur à l'Institut Pasteur.

PREVENTION OF SCARLET FEVER IN SCHOOLS.

To the Editor of THE LANCET.

SIR,—May I be permitted to add to my first letter in view of Dr. Glover and Dr. Griffith's communication. The object I had in mind was, as I stated, to correct the impression which their paper inevitably created—viz., that nothing could be done to stop an epidemic of scarlet fever in a school. Their statement was that passive immunity is too evanescent for use in a boarding school, that it has the disadvantage to sensitise to serum (we have now fortunately Dr. Dunn's account of the use of this method by him at Uppingham, *a boarding school*, for the last three years with complete success, upon which I wish to congratulate him), and that the production of active immunity by the Dick method took too long and was too uncertain; these pronouncements, coupled with their admission that the ordinary

[1] Annales de l'Institut Pasteur, 1913, xxvii., 839.

methods of isolation, disinfection, &c., which were carried out very carefully were disappointingly unsuccessful, and the fact that bacteriology in their hands (and it could not have been done more efficiently) was found to be of no practical value, led to the inevitable conclusion that nothing in fact is of any use to control an epidemic of scarlet fever in a school. I quoted my experience at the day school not for comparison with theirs, but to demonstrate that it had been done; readers will draw their own conclusions and these will naturally vary with their apperceptions.

I referred to the Dicks, and I may perhaps usefully add further that: [1]

"They have had an opportunity to employ this method of controlling scarlet fever in 218 families in which scarlet fever had occurred and in epidemics in four different institutions. No new cases of scarlet fever developed in these families or institutions later than 48 hours after the control of the epidemic was undertaken, except in instances where for some reason it was not possible to follow the prophylactic administration of antitoxin by active immunization with the toxin before another exposure to immune carriers or the return of the convalescent scarlet fever patient to the home."

Such work by the Dicks cannot be dismissed as being of no significance. The uncertainty about active immunity against scarlet fever (which was mentioned) has been shown [2] by Toyoda and Futagi to be due not to the non-establishment of immunity, but to the inaccuracy of the Dick test, as usually performed. They demonstrated that the Dick test toxin consists of a heat labile and heat stabile portion, which they separated, and that the heat labile toxin only is the true indicator of susceptibility to scarlet fever, heat stabile toxin often giving allergic skin reactions, mistaken for positive reactions, in those subjects who were immunised against streptococci or scarlet fever.

But if we have been erring, we have been erring on the right side, assuming, as we did some to be susceptible who were in fact immune, because the negative Dick test with whatever Dick toxin produced did and still does indicate immunity to scarlet fever.

I am, Sir, yours faithfully,

W. EDGE,
Medical Superintendent, Ladywell Sanatorium (Infectious Diseases), Salford.

VALUE OF RAMISECTION IN CASES OF SPASTIC WEAKNESS.

To the Editor of THE LANCET.

SIR,—In his address delivered at the opening of the Banting Research Institute of Toronto University (THE LANCET, Oct. 11th, p. 779) Lord Moynihan was unfortunate in his choice of the researches of Hunter and Royle to illustrate "the somnolence of physiologists."

Hunter and Royle were attracted, as others have been before them, by the idea of a dual innervation of skeletal muscle, and particularly by the suggestion that the sympathetic nervous system might be responsible for the maintenance of postural or "plastic" tone. They performed a number of experiments on goats and pigeons, and they drew conclusions which were entirely at variance with those which had been arrived at by physiologists and others working in the same field. They admitted this, but they claimed that the *clinical* results of sympathetic ramisectomy in human beings were so remarkable that physiologists would be compelled to alter their views on the physiology of muscle and bring them into line with their own.

As soon as this work was published, some of us performed sympathetic ramisectomy in a number of carefully selected cases of spastic paralysis, with every possible precaution against technical error, and we failed to get any results comparable to those claimed by Royle. But, even before we operated on these cases, we were met with the unanswerable argument that anyone who did this operation and failed to get the results which Royle described was either an incompetent surgeon who failed to divide the sympathetic rami, or an indifferent neurologist who could not interpret the signs.

In the face of this argument there was only one thing to do, and we did it. We, a group of orthopædic surgeons and a neurologist, got hold of Royle when he was in this country in 1927. We took him down to Carshalton and gave him a free choice of a large number and variety of cases of spastic paralysis, and of these he selected six which in his considered opinion were suitable for the operation of sympathetic ramisectomy. The selection was made with care and deliberation, since the avowed object of the ensuing operations was to demonstrate to us and convince us of the remarkable results of sympathetic ramisectomy in cases of spastic paralysis. We examined these cases with Royle before operation, we made him operate upon them in our presence, we examined them again with him soon after operation, and lastly we examined them again two years later. The results of these investigations were briefly recorded in THE LANCET of July 19th, and it will be seen that they fail to substantiate in any particular the physiological conclusions of Hunter and Royle.

There, so far as we are concerned, the matter rests. Royle objects to our drawing "sweeping conclusions" from a small number of cases, and he would rather have us accept without question his own estimate of cases which we have not seen and which we have no opportunity of judging on their merits. We, however, prefer to believe the evidence of our own senses, and reports of hundreds of "successful cases" from America and elsewhere leave us cold.

In your issue of Nov. 29th Royle reiterates his one and only reply to criticism—namely, that we are incapable of doing the operation or of interpreting the results. He starts badly by repudiating his one-time friend and colleague, J. I. Hunter, since he objects to our coupling the name of Hunter with his own. We are aware that Royle got his first paper into print a few months before Hunter published his. But, in this same paper, which lies before me as I write, Royle says:—

"In conclusion, I wish to express my indebtedness to Prof John I. Hunter for his assistance in arranging the plan of experiments and for his constant advice and help in interpreting the results obtained. He also rendered invaluable assistance in planning the surgical operations. The experimental work was carried out in Prof. Hunter's laboratories."

We may not agree with the physiological conclusions of this brilliant young anatomist, but those who know the work of both these men have little doubt that the operation of sympathetic ramisectomy would never have originated in Sydney without the help and inspiration of J. I. Hunter.

Royle now asks us "which operation in the lumbar region produces a diminution of tone in the lower limbs and for what length of time?" The answer, as he well knows, is any major operation, and for

[1] Acute Infect. Diseases, Schamberg and Kolmer, p. 461.
[2] Jour. Infect. Dis., March, 1930, p. 196.

about a week or more. In his original paper already referred to (page 10 of the reprint) he writes:—

"The handling of the tissues in this (the lumbar) region could profoundly affect reflex activity within a few days following the operation and the changes then seen could not necessarily be ascribed to the removal of the sympathetic trunk."

This is precisely what we have observed both in our own cases and in those operated upon by Royle. But we have allowed for this obvious source of error in estimating the end-results of his cases, while he has not. He says, for example, that in Case 4 of our report "Ramisection produced *immediate* improvement in range of movement and alteration in reflexes." We know it did, but that has nothing to do with the end-result which was a complete failure. Some at least of the records which have been used to illustrate the results of ramisection were taken within a few hours of the patient's coming round from the anæsthetic, and to our knowledge the temporary improvement then noted has not been maintained.

The time has come for plain speaking. (1) The operation of sympathetic ramisectomy for the *relief of spastic paralysis* is based upon an unsound physiological research, and it is a complete failure. (2) It has been "boosted" as I believe no other operation has been in our time. (3) Faultlessly performed by Royle himself in cases of his own selection, it has under accurate observation entirely failed to vindicate the claims which he has put forward for it. There is no evidence that the sympathetic nervous system is responsible for the maintenance of postural or "plastic" tone in skeletal muscle, and division of the sympathetic rami communicantes does not confer any lasting benefit on patients suffering from spastic paralysis. There would therefore appear to be no justification for its performance in such cases. (4) Royle, with the "invaluable assistance" of J. I. Hunter, devised a technique for dividing the sympathetic rami communicantes. This is a purely technical achievement and has nothing whatever to do with physiological research. Every student knew before that division of sympathetic nerve-fibres would produce a corresponding vasomotor paresis, though, I would add, this is not necessarily obvious in the coarse skin of some hospital patients. (5) It may well be that sympathetic ramisection has proved or will prove to be of benefit in certain cases of vascular disturbance and perhaps in some other conditions, such as arthritis, in which a more or less permanent vasodilatation would appear to be desirable. But this again has nothing to do with the physiological problem of postural or "plastic" tone in skeletal muscle.

I am, Sir, yours faithfully,

A. S. BLUNDELL BANKART.

Harley-street, W., Dec. 6th, 1930.

DIAGNOSIS OF PULMONARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—In his Mitchell lecture Dr. Burrell shows how each symptom of tuberculosis settles down into a truer and saner place. Take hæmoptysis, for example; even 20 years ago this was treated with ice-bag and absolute rest; to both physician and patient it was almost the signal for the nearest undertaker. Look at the picture now. The advent of artificial pneumothorax, done with the promptitude made possible by the motor-car, has completely changed the outlook for a majority of cases. I cannot agree with Dr. Carver that the physician is apt to be misled by hæmoptysis resulting from gingivitis; if Dr. Burrell's common-sense way of dealing with a case is employed the diagnosis should be simple enough. We have, indeed, materially advanced in our conception and treatment of pulmonary tuberculosis in spite of what is said so often to the contrary.

I am, Sir, yours faithfully,

J. D. MACFIE.

Winsley Sanatorium, near Bath, Dec. 3rd, 1930.

To the Editor of THE LANCET.

SIR,—We should all be grateful to Dr. Burrell for his excellent summary of the chief diagnostic points in pulmonary tuberculosis. I am particularly glad to see his reference to the value of a negative sputum. It has always appeared to me very unlikely, after carefully examining a "real pussy spit" two or three times, and finding it negative for tubercle bacilli, that the underlying lung trouble was tuberculous.

I would be grateful for an opinion from some authority as to the importance to be attributed to one symptom not mentioned by Dr. Burrell. I refer to disturbance of the menstrual function. It may be said that there are many other diseases which cause this symptom, but then the same thing may be said of cough. When a young girl comes to me with some of the other symptoms of the disease, and in reply to a leading question about her menstrual health, says that there is some disturbance (usually absence), I take it as a point in favour of a positive diagnosis. On the other hand, if she says she is all right that way, and if, nevertheless, she is diagnosed as pulmonary tuberculosis, I would expect her to do better than a similar case with amenorrhœa.

I am, Sir, yours faithfully,

P. J. BURKE,
County Tuberculosis Officer, Sligo.

Central Tuberculosis Dispensary, Sligo, Dec. 3rd, 1930.

OCULAR NEUROSES AND SO-CALLED EYESTRAIN.

To the Editor of THE LANCET.

SIR,—Your annotation on Dr. G. S. Derby's paper (THE LANCET, Nov. 22nd, p. 1136) raises questions affecting public policy which need an authoritative answer. Dr. Derby is not the first to point out that eyestrain is not responsible for many of the troubles usually accredited to it. His distinguished countryman, Dr. J. J. Putnam, expressed the same views over ten years ago. In regard to treatment Dr. Derby says it is rarely necessary to call in a trained psychologist. That may be so in private practice, but it is an interesting speculation as to what would be the result of the examination of (say) the 140,000 school-children for whom, according to a statement made in the House of Commons last month, glasses were provided in 1929, if a trained psychologist were asked to separate the sheep of unblemished ophthalmic importance from the goats of neurotic ophthalmic masquerading. Dr. Millais Culpin, an unprejudiced and cautious observer, in his investigations on behalf of the Industrial Fatigue Board, has for a long time accepted the wearing of weak convex glasses for distance as a symptom of a neurotic disposition. I much doubt if the complacency of

orthodoxly conducted eye departments of school clinics would survive his report. There are certainly many cases in my department which I should dearly like to pass on to the trained psychologist.

Further, now they are getting hard up, the friendly societies might with advantage ask for such a report on their members before spending their money so freely on optical benefit without expert guidance. Lastly, it might cause those responsible for the public weal to hesitate before letting loose State-registered opticians upon a public already deluded by a medical myth. Let it not be forgotten that only a few years ago serious claims were being made that miners' nystagmus was due to errors of refraction. Yet no one smiled.

I am, Sir, yours faithfully,

Portsmouth, Dec. 7th, 1930. W. S. INMAN.

THE CHARTERHOUSE RHEUMATISM CLINIC.

To the Editor of THE LANCET.

SIR,—Dr. Congdon has set forth certain figures which emerged in the attempt to determine the value of vaccine treatment in cases of rheumatoid (infective) arthritis. Very little difference is shown between the treated cases and the controls, a result which is in full accord with the adverse opinion generally held in regard to the method. In her series of 330 cases, vaccine treatment failed. Assuming that this failure was not due to technique, bacteriological or nosological, then her figures are confirmatory of the view (which I first published in 1914) that true rheumatoid arthritis is not primarily caused by a streptococcus but by a white staphylococcus, which I then named the *S. epidermidis albus* var. *deformans*, or more shortly the *Micrococcus deformans* (of which, as Dr. Graham-Bonnalie states in his letter of last week, there are two types). If my view is correct, then failure to benefit the disease by vaccines of a non-causative organism, such as a *Streptococcus viridans*, has no bearing whatsoever on the value of specific vaccine treatment. It merely serves to show that non-specific vaccines are of no great value in the treatment of this type of disease.

My personal experience is the exact opposite of Dr. Congdon's. Rheumatoid arthritis responds extremely well to vaccine treatment, and if taken in time should never fail to be cured. The sooner this fact is recognised the better, for, with the exception perhaps of osteo-arthritis of the hip-joint, there is no form of rheumatic disease so refractory to ordinary treatment, or more frequently made worse by misguided attempts at alleviation. Nor is there any disease which is more terrible in its results—attacking as it does young people in the prime of life and turning them into bedridden cripples. Fortunately, however, true rheumatoid arthritis is a comparatively rare disease. Only about 5 per cent. of the cases at the Charterhouse Rheumatism Clinic are of this type. Of these all the early cases have done well, and even some advanced cases have recovered sufficiently to resume their occupations. Dr. Congdon's criterion of "improvement before treatment" does not apply at the clinic, as all cases, practically without exception, are getting worse when they first attend. Then there is the question of environment. The advantage here is all on the side of the Devonshire Hospital. Patients, whether in the wards or attending as out-patients, must mostly be away from their usual surroundings, whereas those attending the Charterhouse clinic, if too crippled to carry on their ordinary avocations, are at least living in their usual, often most unfavourably situated homes.

Osteo-arthritis, mixed arthritis, and fibrositis constitute the enormous majority of our cases, but in Dr. Congdon's opinion these types are too diversified for examination by the usual mathematical methods, and could not count in any case because their infectious nature is not generally recognised. Nor was that of tuberculosis 50 years ago. The medical staff at the Charterhouse clinic is working on the hypothesis that osteo-arthritis and fibrositis are infective diseases and as such should be amenable to vaccine treatment. The answer to the objection that no statistical judgment is possible surely must depend on the form of treatment to be judged. Where this is expectant or entirely symptomatic, diverse types must be recognised for statistical purposes. But in specific vaccine therapy the classification becomes bacterial and types no longer matter. For example, lobar pneumonia and an arthritis due to pneumococci, however diverse in type, could both be classified statistically as pneumococcal infections. In the same way at the Charterhouse Rheumatism Clinic we group osteo-arthritis and non-articular rheumatism as mainly streptococcal diseases, and rheumatoid arthritis as mainly staphylococcal, thus not only simplifying the whole conception but rendering all types, however diverse in appearance, suitable for simple statistical treatment.

As evidence in favour of the bacterial hypothesis we adduce our experience that, almost without exception, "reactions" follow individual doses of streptococcus vaccine in nearly every case of osteo-arthritis and of fibrositis, just as occurs in the tuberculin test, but—and this adds to the significance—with very much smaller doses when measured in dried weight of bacterial content. We are completely satisfied that the results at the clinic are due to our making this hypothesis the basis of our treatment. Added to this, as Dr. Graham-Bonnalie says, we have recognised that the whole body may be involved in the rheumatic process, in consequence of which dosage must be far lower than it would be in any less generalised complaint.

I am, Sir, yours faithfully,

H. WARREN CROWE, D.M., B.Ch. Oxf.

Portland-place, W., Dec. 8th, 1930.

TWINNING IN MONGOLISM.

To the Editor of THE LANCET.

SIR,—Dr. Coupland asks for the number of known instances of twin-births, in which one twin is mongoloid and the other normal. The best recent paper is, perhaps, that by Macklin (*Amer. Jour. Med. Sci.* 1929, clxxviii., 315), in which a list of about 38 such are given; but lately others have been added. There is, however, reason to believe that the number of cases known is but a fraction of those that have occurred during the last 30 years. It is desirable that anyone reporting future instances should remember the three distinctions that can be made. Thus: the birth may be (1) uniovular or binovular (2) heterosexual or homosexual; and (3) monomongoloid or bimongoloid. Monomongoloid twin births are, apparently, always binovular, but may be heterosexual or homosexual. It should be, but is not, superfluous to insist that a reporter should always give his reason for considering a particular twin to

be "normal" or mongoloid. Unfortunately, it is becoming fashionable to describe as a "mongol" almost any child of undifferentiated ethnic type with general fœtal characteristics, in forgetfulness of Langdon-Down's own definition of the class he described. This definition it is our duty and our right to conserve.

The question of twinning in mongolism is discussed at some length in an entirely rewritten version of my book "The Mongol in our Midst," which will be published by Messrs. Kegan Paul and Co., in a few days.

I am, Sir, yours faithfully,

F. G. CROOKSHANK.

Wimpole-street, W., Dec. 6th, 1930.

MEDICINE AND THE LAW.

Statistics of Criminal Abortion.

THE Criminal Statistics for Scotland for the year 1929 (recently published as Cmd. 3699) give the usual tabular information as to the common-law offence of procuring or attempting to procure abortion. The total number of cases made known to the police in the year was seven. One man and six women were proceeded against; one woman was discharged and not called for trial, another was released on a verdict of "not proven." The rest were convicted and sentenced to imprisonment or in one case penal servitude. The Scottish statistics of criminal abortion are low. The average number of such crimes charged annually in the quinquennial periods ending in 1914 and 1924 was only 2 and 5 respectively; the total of such charges for the past five years have been 4, 9, 5, and 7. For England in the corresponding quinquennial periods ending 1914 and 1924 the figures for this offence known to the police were 40 and 48, while the number of persons actually tried was 30 and 2. The 1929 statistics for England are not yet available. The annual totals for the years 1925 to 1928 are far more substantial than the Scottish totals—namely, 86, 55, 74, and 113 known to the police; and 62, 41, 44, and 74 persons actually brought to trial. The introduction to the English Criminal Statistics for 1928 admits that the rise in 1928 over the quinquennial average for 1910–14—(i.e., the rise from 40 to 113) "no doubt reflects a real increase in this offence."

Criminal abortion is notoriously an offence difficult to prosecute to conviction. It is not committed *coram publico;* the women who have employed the services of an abortionist are reluctant to come forward, and, when they do, their evidence requires corroboration because they are in a sense accomplices with the accused person. It is thus the less surprising that in England in 1928 only 74 cases were brought to trial out of 113 known to the police, and only 57 out of the 74 prosecutions resulted in a verdict of guilty." Out of this array of figures the simple fact emerges that, in the latest year for which statistics are available, there were only 57 criminal abortionists in England and only five in Scotland. If the medical practitioners of Great Britain met in camera to estimate a total in the light of their own information and strong suspicions, what would that total be?

Unsuccessful Action for Medical Fee.

A medical practitioner obtained judgment against a widow in the Bow County Court for £1 11*s.* 6*d.*, his professional fee for attendance on her late husband. Last week the defendant applied to set aside the judgment and to obtain a new trial. According to her statement her husband had been taken ill at 3 A.M.; she had sent in to her next-door neighbour to fetch the panel doctor. Another practitioner arrived half an hour after her husband had died; the widow stated that she at once told him that he was the wrong doctor. The practitioner who was thus brought on the scene and who had made the claim for an attendance fee was unable to say who had sent for him; he understood the police had been called in. Judge Owen Thompson, K.C., said that without question the plaintiff practitioner had earned a fee from somebody; the question was from whom. His honour said it looked like a police call. He sympathised with the practitioner, but the circumstances did not make the widow liable. If, said his honour, I grant the widow a new trial, the practitioner does not stand much chance of winning, as he was not called by the widow's authorised agent. In the circumstances the plaintiff doctor decided not to proceed with the action. The judge seems to have assumed that the practitioner was called in by the police; if he had been called in by the next-door neighbour, he would presumably have been summoned by the widow's authorised agent.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

THE following appointments are announced: Surg. Lt.-Comdr. C. H. Savory to *Pembroke*, for R.N. Hospital, Chatham; Surg. Lt.-Comdr. (D.) F. W. Paul to *Pembroke*, for R.M. Infirmary, Deal; Surg. Lts. W. C. Sloan to *Warspite;* G. D. J. Ball to *Victory*, for R. M. Infirmary, Portsmouth; and G. A. Miller to *Dahlia.*

ROYAL NAVAL VOLUNTEER RESERVE.

Lt.-Comdr. L. L. Withrington to *Champion.*

Proby. Surg. Lt. (D.) F. J. Goldsworthy to *Victory*, for R. N. Hospital, Haslar.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. B. H. V. Dunbar, from R.A.M.C., to be Col., vice Col. A. H. Safford, to retd. pay.

Maj. A. H. Bond to be Lt.-Col., vice Lt. Col. B. H. V. Dunbar, promoted.

Capt. L. Game relinquishes his temp. commn.

Temp. Capt. Michael J. Whelton to be Maj.

ARMY DENTAL CORPS.

W. E. Duckworth to be Lt. (on prob.).

ARMY RESERVE OF OFFICERS.

Lt. L. P. Clarke from Reg. Army Res. of Off., Norfolk Regt. to be Lt.

TERRITORIAL ARMY.

Maj. F. R. Harris to be Lt.-Col. and to comd. 140th (C. of Lond.) Fd. Amb.

Capt. G. Whittaker to be Maj.

Lt. W. H. G. Park to be Capt.

DEATHS IN THE SERVICES.

The murder of Lt.-Col. Norman Skinner Simpson, I.M.S., on Monday last has been announced by telegram from Calcutta. The murder took place in the premises of the Bengal Government, where the offices of the various heads of the departments are situated. According to one report, the murder of Col. Simpson may have been due to the accident of the location of his room, but it must be remembered that previous to his appointment as Inspector-General of Prisons in Bengal, he had been a superintendent in the Gaol Department, and may have been a marked man among fanatics. Col. Simpson, who had a fine professional record, was only 49 years of age.

Surg. Capt. R. J. Willan, M.V.O., O.B.E., V.D., Royal Naval Volunteer Reserve, has been appointed an Honorary Surgeon to the King, vice the late Surg. Capt. A. R. Brailey, V.D.

OBITUARY

FRANK EDWARD NICHOL, M.B., B.Chir. Camb.

WE regret to announce the death of Dr. Frank Nichol, the well-known Margate practitioner, which occurred on Nov. 28th at his house in Cliftonville.

Frank Edward Nichol was born in 1861, was educated at Dulwich College and Caius College, Cambridge, and made a mark both at school and college as an able student and a vigorous athlete. He proceeded from Caius to St. Thomas's Hospital, took the double English qualification in 1885, and graduated M.B., B.Chir. Camb. two years later. He served as house surgeon at his hospital, and also as clinical assistant in the dermatological department, after which he took up his residence in the town where he has died, to the deep regret of a neighbourhood which he had served faithfully for 40 years. For while attending assiduously to a large private practice he found time to be a leader in all the movements for the welfare and progress of the town. His gift of public speaking, and his musical talent stood him in good stead in these public movements. For many years he was surgeon to the Margate Hospital, and on the medical staff he was a tower of strength. He was medical officer to the Royal School for the Deaf, to the West Ham Union Convalescent Home, the Victoria Home for Invalid Children, and the Royal Sea Bathing Hospital, and at every one of these institutions he earned appreciation not only for ability but for generosity in attitude and action. The erection of the new Margate Hospital, a development of the old Cottage Hospital, was largely due to Nichol's recognition that such an institution was needed to meet the growing population of Margate, and especially the increasing motor traffic. He worked hard and well on behalf of the new venture, and the success of the scheme from the beginning was greatly due to his public and professional qualities. With the hospital he had been officially connected since his election to the staff in 1897, and his retirement was the occasion of an eloquent expression of admiration from the committee of management, at whose instance one of the wards was named the Nichol ward.

Although he took no part in municipal administration he was a valued counsellor of those who did, and so clearly was he marked out as a man of affairs that the proposal was made to him that he should offer himself as the representative of the Isle of Thanet in Parliament. From the party point of view the idea was a thoroughly sound one, and Nichol's candidature would probably have been followed by a successful election, but he considered that parliamentary duties would have been impossible without relaxation of other energies, which he held to be impossible. He was on the borough bench of magistrates, had been president of the Margate Chamber of Commerce, and a valued member of the Rotary Club. During the war he may be said to have almost lived in the hospital when the younger men were necessarily absent, a devotion which was recognised by his election as President of the hospital, and in addition to his professional duties he found time to go into training, as an honorary captain, with the South Eastern Mounted Brigade, Field Ambulance, R.A.M.C. Dr. Nichol's death followed a considerable period of ill-health, though it occurred just as he returned to work. He married, in 1891, Annie Lilian Price, the daughter of Dr. William Price of Margate, who survives him, and by whom he had four children—three sons and one daughter. The second son was killed in the war, and the third died just after the war, while the eldest son, Dr. Robert Nichol, was a partner in the Margate practice. Dr. Nichol's daughter is married in Rhodesia.

ANDREA RABAGLIATI, M.D., F.R.C.S. Edin.

Dr. Rabagliati, who died at Ben Rhydding on Sunday in his eighty-eighth year, was one of the best known figures in Bradford for 50 years or more. His father was an officer in the Italian army, who sought refuge in Scotland after an unsuccessful revolt against Austrian rule. Capt. Rabagliati spent some time in the manse at Kelso, read Italian with Sir Walter Scott at Abbotsford, married a Highland lady and settled in Edinburgh, where Andrea Carlo Francisco was born in 1843. Andrea was educated at Edinburgh High School, went to a clerical uncle in Demerara for two years, and returned in 1862 to study medicine at Edinburgh University. He graduated with honours in arts in 1867 and in medicine in 1869, taking the M.D. three years later with gold medal for a thesis on relapsing fever. On graduating he went as assistant to Dr. Leeson, medical officer to the Bradford workhouse. At that time Bradford had less than half its present population and, as Dr. Rabagliati used to say, appeared to consist of a few employers and a large number of employed. After two years as house surgeon to the infirmary he began practice on his own account, soon becoming hon. surgeon to the infirmary, assistant surgeon to the Eye and Ear Hospital, and medical officer to the Fever Hospital. In conjunction with Dr. Burnie and Dr. Harry Meade he helped to found in 1882 the Children's Hospital in Hanover-square, which was the nucleus of the present hospital built and opened in 1890. He was instrumental in founding, with his wife's untiring help, St. Catherine's Home for Cancer, to which he was appointed consulting surgeon. He was also consultant to the Bingley Hospital, the Actors' and Music Hall Artistes' Associations, and consulting gynæcologist to the Bradford Royal Infirmary.

Although holding surgical appointments, Dr. Rabagliati's bias was always towards medical practice, especially on questions of diet. The publication of his numerous medical books brought him a large consulting practice on these lines, and he was frequently urged to confine himself entirely to such, but he believed he could do more good by the general care of patients, although latterly consulting work and ever-increasing correspondence left him time for little else. He continued to practise without intermission, taking but few holidays, from 1872 up to his eighty-seventh birthday in May, 1930, when he was first taken ill.

In 1877 Dr. Rabagliati married Helen Priscilla, youngest daughter of the late Duncan McLaren, M.P. for Edinburgh, by whom he had four sons and one daughter. His eldest son, who practised surgery in Natal and Nairobi, died last year. Another son is a veterinary surgeon.

Dr. Halliday Sutherland writes: "Dr. Rabagliati was remarkable alike for his character and ability. He lived beyond the allotted span, and early in his life had sacrificed a large practice by reason of his views

n diet, which were not then appreciated either by his ollеagues or by the public. Yet he held these views o the end of a long life, and lived to see Guelpa, of aris, introduce a method of detoxication based on rinciples in no way different to his own. By diet, more accurately, by starvation, Dr. Rabagliati otained many remarkable results in chronic ailments. s his views made headway, practice gradually turned, and even during the past year patients had me from America to consult him. He published veral works which never made a wide appeal. is was partly due to the style in which they were itten. They reminded one of the spacious days of denham, when men wrote leisurely and at length. e had also a fondness for coining new words, based Greek roots, which were rather puzzling to those thout a classical education. His interest in medicine as maintained to the end, and what hurt him even re than the malady of which he died was the owledge that it interfered with his practice. When e rôle of the lymphatic system in the causation of ease is better known Rabagliati will be remembered a pioneer."

THE LATE DR. BILAND OF DAVOS.

Dr. J. Biland, who died in his sleep on Oct. 28th, had been medical director of the Davos Dorf Sanatorium since 1916, and was one of the directors of the Swiss Institute for Medical Research at Davos. Born in 1877, in the Canton of Glaris, he was educated at Neuchâtel and studied medicine at the Universities of Zürich and Berne. He was then, in succession, assistant to Kocher, at Berne, and Lichtheim, at Königsberg. He passed the Italian State examinations when he was in charge of the Sanatorium Ambri Piotta. At the outbreak of war he worked at a German Red Cross hospital with Dr. Bernhard, of Samaden. On his return to Switzerland he was appointed medical officer to the interned prisoners who were stationed at Davos, and a considerable number of British officers were sent to his sanatorium at Davos Dorf by the British Red Cross Society. Dr. Biland was an able and popular lung specialist who enjoyed the affectionate regard of patients of many nationalities. He spoke nearly all European languages fluently.

PANEL AND CONTRACT PRACTICE

"A Second Opinion."

THE question of how best to safeguard the funds friendly and other sickness societies continues occupy much space in their official review. The *tional Insurance Gazette* published last week a ther instalment of Sir Alfred Watson's address the Institute of Actuaries, which dealt with work of medical referees under the National alth insurance system.

"It would have been difficult," Sir Alfred said, few years ago to urge on friendly societies, with success, the advantage of obtaining a 'second nion' in cases of doubt as to the genuineness of apacity, but in view of the establishment by the istry of Health of a corps of 'medical referees' whose services there is a wide and growing resort the approved societies, this instrument of control become familiar, and the actuary who is called n to deal with the consequences of a heavy rate ickness should not find it difficult to press for its lication in doubtful cases. It is, however, ndantly clear that friendly societies cannot rd, and probably never will be able to afford, to ard the additional weapon of defence with which reduction of sickness benefit in protracted cases s them."

aking up this point in its editorial columns the *tte* remarks: "A good many societies, mainly e operating in a restricted area around their tered offices, can, with advantage, employ a ical officer of their own. This officer does what kness visitor does, and does it better. Claims ubmitted to him on receipt, and within 48 hours otifies the result of his investigation—perhaps ally in the first instance (to save delay) but equently in writing, because documentary nce will be required in the case of disputes. know at least two societies which employ such cal officers—and with a very great saving to funds. Obviously, there can be no better way eeting the short duration claimant, who is such nace."

Sickness Benefit on Tyneside.

a recent meeting of the Newcastle-on-Tyne ance committee it was reported that the 108,000 insured persons in the county borough shared 539,342 prescriptions, dispensed by panel chemists at a cost of £17,290, and incurred doctors' fees of £48,100. Anxiety was expressed in the committee at the increasing cost of sickness benefit. The panel committee has, however, made it clear that there is in their opinion no question of malingering. According to the *North Mail* a representative of this committee has said:—

"The increased cost is due in no small measure to the pressure of economic circumstances on insured persons, who formerly would not go to their panel doctor for free treatment, but preferred to consult another doctor and pay as private patients. That prejudice against the scheme has been broken down now. What is more, it is due in part to officials of approved societies who send their members to us to demand benefits to which they are not necessarily entitled. People are now thoroughly acquainted with the Act, and are seeking benefits of which formerly they had no knowledge. We claim that the actuarial calculation of sickness was wrong in the first place.

"The costs," he went on to say, "are not as heavy as they ought to be. Men receiving the dole draw the employment exchange benefits as long as they can, then come to us for a few weeks and get sickness benefits during the employment exchange 'waiting period,' and, when that is ended, they return to the dole. Those men are not malingerers. They are not getting anything they are not entitled to. They ought to be receiving sickness benefits all the time, and would be doing so if they could afford to sacrifice the dole, which is on a higher scale. They are not physically fit for work."

HOSPITAL ACCOMMODATION AT STOKE-ON-TRENT.—On Friday last Mr. Arthur Greenwood, the Minister of Health, laid the foundation-stone of extensions to the Hartshill Maternity Homes. The scheme is of considerable dimensions, but the immediate enlargements will comprise 60 beds and a new theatre. On the same day Mr. Greenwood opened a new cubicle block at the infectious diseases hospital at Bucknall, which has been erected by the Stoke-on-Trent City Council. The block, which has cost £5750, contains 12 single-bed cubicles. At present this hospital has 192 beds in 14 wards, and when the scheme of enlargement is completed there will be 282 beds.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS.

ACCIDENTS IN MINES.

IN the House of Commons on Wednesday, Dec. 3rd, Mr. SUTTON moved :—

That this House deplores the heavy loss of life and the large number of non-fatal accidents in coal mines and urges the Government to take every possible measure for the protection of those engaged in this dangerous industry.

He said that the number of deaths and accidents in the mines was increasing every year. H.M. Inspector of Mines in his report for 1929 stated that 985 persons working underground were killed, an increase of 100 over the previous year. The number injured underground was 162,230, or an increase of 13,098 on the previous year. The Secretary for Mines in reply to a question had stated that over 800 deaths had occurred in the mines during the ten months of 1930. A large number of committees had been inquiring into this matter for some years past, but not much progress had been made ; in fact they seemed to be going back. In the report of His Majesty's Inspector for 1929 it was stated that there were 12,651 persons injured on the surface, or an increase of 837 as compared with the previous year. There were in the mines of this country 29,000 boys under 16 years of age working underground. Last year the number of boys under 16, according to figures given by the Chief Inspector of Mines, who were killed or injured was at the rate of 251 per 1000 boys employed. In the case of boys between 16 and 18 the rate was 230 per 1000, and of those between 18 and 20 223 per 1000. In the case of those aged 20 and over the rate was 209 per 1000, while for all ages it was 212 per 1000. He hoped the Secretary for Mines would make a note of these facts. During the past eight and a half years some 10,440 persons had been killed in the mines of this country, or an average of well over 1000 a year. In those eight and a half years 1,587,330 persons were injured in the mines, apart from the 10,440 who were killed. He earnestly appealed to the Government to investigate this matter very carefully, particularly as it affected the boys.

Mr. TINKER, in seconding the resolution, said that if the law was carried out with regard to ventilation in the mines many of the accidents would be prevented.

After further debate,

ASCERTAINMENT OF CAUSES.

Mr. SHINWELL (Secretary for Mines) said he was as anxious as any miner or any Member of the House to promote the well-being of the mining industry and the safety of the miners, and he desired as a line of approach to a solution of the safety problem to secure the coöperation of both sides of the industry, and to focus the attention not only of mining officials but of miners themselves on the various aspects of this problem, more particularly in relation to the proper observance of the regulations laid down by the Department. He did not question the figures which had been given in the debate. He was more than familiar with statistics relating to the mortality-rate among miners, and the remarkably high accident-rate. He was deeply concerned about the matter, particularly in view of the fact that in recent years he detected not a diminution, but an increase in the rate. Although progress had undoubtedly been made in the direction of promoting safety they could not regard the existing condition with complacency. He was far from complaining about the orthodox methods employed by the industry and his Department in recent years. They had all tended to promote greater safety, but relatively speaking they found in the official figures a higher accident-rate and a higher mortality-rate—much too high a rate in the circumstances. If they were to approach this problem wi a view to finding as complete a solution as possib they must first ascertain the cause of the accident Recently in his spare time he had analysed t principal types of accidents occurring in the mine He found that the majority of accidents occurred a result of the fall of roof or side. The second ma cause of accident, which applied also to the mortalit rate, was haulage. The third was due to explosio of coal dust or fire damp, and these were relative low.

He was not concerned about defending what w now being done for the promotion of safety in t mines except to say that he believed considerab progress had been made, and that no complai could be laid at the door of the Inspectorate of t Department. To find a remedy the first thing requir was to secure the greatest measure of coöperation the industry, and in that he had succeeded in son measure. As far as the employers were concern there was every reason why they should coöperat They paid in 1928 in compensation £3,026,678, a he understood that that was almost 50 per cent. the total amount paid in workman's compensati in the seven great groups of industries in this count for which returns were obtained under the Act 1925. That meant something like fourpence or fiv pence a ton on coal, and when they spoke of t burdens resting on the coal industry they mig consider that particular burden. The Miners' Feder tion had agreed to set up a subcommittee to a with officials of the Mines Department in the di cussion of the problem. That subcommittee ha already dealt with a variety of subjects. The Mini Association had responded most readily that the should coöperate in the discussion of the proble They had set up a subcommittee, but only o meeting had been held to date. They had dealt wit silicosis and other important matters. This coöper tion between employers, the miners, and his Depar ment would continue. He did not wish at this sta to press either side unduly in a direction of reachi decisions, although wherever the Department sa points of agreement they would utilise them.

ILLUMINATION AND NYSTAGMUS.

Sir HENRY BETTERTON : Are the non-ferrous min like tin and lead represented, or only coal mines ?

Mr. SHINWELL said they were dealing with co mines alone, but he would be very happy if the requested him to give consideration to the no ferrous mines. He thought it was desirable to ha more education in relation to safety. There cou be no doubt that one cause of accidents in min was the familiarity with conditions. It was essenti to promote greater care. It was impossible at th stage to promote further mining legislation. The had succeeded in taking a definite step in one part cular direction—namely, the provision of mo efficient illumination in the pits. So far as researc had gone, although there was a difference of opinio it was generally agreed that nystagmus cases we attributable to deficient lighting. It had been su gested that to some extent they might be due the stooping posture adopted by miners and the g in the pits. That might be so, but the bulk of scienti opinion on this subject held the view that inefficie lighting was the primary cause. Therefore th were devoting some attention to the question better illumination. A Draft Order was to be su mitted to the industry for their discussion, and hoped their endorsement. These new proposals relation to mine lighting aimed at a general improv ment in the standard of lighting in three princip directions. First of all there was the raising of t minimum candle power standard of miners' safe lamps, not only the flame lamp but the electr lamp also. They proposed to provide a relaxati

the present drastic statutory restriction upon ethods of lighting other than safety lamps. That as full of difficulties, because there was a dispute to whether the use of electricity in the pits was sirable. They also proposed to secure, if they uld, definite provision for a reasonable standard of rface lighting which hitherto had not been regu-ted by law except for railway shunting operations. ey also proposed to deal with the qualifications of lliery officials generally.

Instead of appointing new inspectors at this stage thought it would be better to relieve the inspec-rate of much of their present work which had no lation to safety at all. If he had his way he would ohibit the employment of boys in mines, certainly der the age of 16, but there were economic causes erating which could not be ignored. He hoped to nsider very shortly the possibility of establishing me form of training for boys. In regard to research, st year there was spent out of the Miners' Welfare nd by the Safety in Mines Research Board more an £50,000 in research. If he found by practical sts that the Ringrose, or any other gas detector, uld be used to benefit the miners, and to secure eater safety in the mines of the country, either by compulsory Order, or by inducing the owners to cept it voluntarily, he would certainly take action. The resolution was agreed to without a division.

HOUSE OF COMMONS.

WEDNESDAY, DEC. 3RD.

Tuberculosis in the Navy.

Mr. MARKHAM asked the First Lord of the Admiralty at number of engineer rating artificers and chief engineer ing artificers had been invalided out of the Service ring 1930 owing to tuberculosis; and whether, seeing at three of them in H.M.S. *Rodney* had been invalided ring the months of August to October, 1930, he could whether the conditions on board were a contributory use.—Mr. ALEXANDER replied: Two chief engine-room ificers, six engine-room artificers, and one apprentice gine-room artificer were invalided from the Service ween Jan. 1st and Oct. 31st, 1930, on account of tuber-osis. Of these one case was of non-pulmonary tuber-osis. As regards the latter part of the question it is considered that the conditions on board are a contri-ory cause, as returns received from the ship to date icate that the general health of the ship's company is y good. Moreover, *Rodney*, one of our latest battleships, constructed entirely in accordance with the most modern nciples and ideas in regard to ventilation and hygiene.

THURSDAY, DEC. 4TH.

Training of Unemployed Women as Nurses.

Sir NICHOLAS GRATTAN-DOYLE asked the Minister of bour how many women had availed themselves during past 12 months of the special provision for the training suitable unemployed women in domestic service, hospital l child nursing, and similar useful occupations, and what l been the result in terms of subsequent employment.—s BONDFIELD replied: The number of women and girls , during the year ended Nov. 24th, 1930, entered train-under schemes controlled by the Central Committee on men's Training and Employment was 4501. During the e period 3635 trainees entered domestic or other work. number in training on Nov. 29th last was 1168.

Local Authorities and Hospital Accommodation.

Mr. JAMES GARDNER asked the Minister of Health if he uld furnish a return for the latest possible date of the nbers and beds, on the lines of the return given in the use of Commons on Dec. 12th, 1929, for hospitals pro-ed by local authorities, with separate figures of insti-ions formerly provided by the poor-law authorities, untary hospitals aided by local authorities, and unaided untary hospitals, giving, if possible, expenditure in each s.—Mr. GREENWOOD replied: The table shows the ition at March 31st, 1930, with the exception of hospitals acute infectious diseases for which the latest available res relate to Dec. 31st, 1929. So far as general hospitals concerned, the information in my Department is that large general hospital, with 875 beds, and three rela-ly small accident hospitals were provided by local horities at March 31st last. Since that date 17 hospitals, h approximately 12,500 beds, which were provided under the Poor Law Acts, have been appropriated as general hospitals under the Public Health Acts, but the expenditure on these hospitals for the year 1928–29 is included in Part *c* of the table below. There are also three poor-law institutions or infirmaries of which parts only have been appropriated as general hospitals. The number of beds in the appropriated parts is not known. Subscriptions or donations made by local authorities in pursuance of Section 64 of the Public Health Act, 1925, amounted in 1928–29 to £30,000. Contributions made by boards of guardians to public hospitals with the consent of the Minister of Health, in pursuance of Section 38 of the Poor Law Act, 1927, amounted in 1928–29 to £38,000.

The information with regard to hospitals of the other classes in England and Wales referred to in the question is as follows:—

(*a*) *Hospitals provided by Local Authorities.*

	Number.	Beds.	Expend. 1928–29.‡
(1) For tuberculosis	166	12,804	£1,865,000*
(2) For acute infectious diseases	987†	36,635†	£3,620,000†
(3) Maternity hospitals (not including maternity wards in general hospitals or poor-law institutions)	80	1040	£268,000§
(4) Babies' hospitals	9	233	

* Including the expenditure in connexion with beds for tuberculosis mentioned in the following note. † At 44 of these hospitals there are 2200 beds for the treatment of tuberculosis. The expenditure on these beds is excluded from item (2). ‡ Expenditure (in round figures) of local authorities in 1928-29. § Including expenditure in respect of maternity sections in general hospitals, and payments to homes for unmarried mothers and their babies, which cannot be separated.

(*b*) *Voluntary Hospitals aided by Local Authorities.*

	Number.	Beds.	Expend. 1928–29.‡
(1) Tuberculosis hospitals	139	9298	
(2) General hospitals—			
(*a*) Used in connexion with tuberculosis schemes	166	—‖	£821,000¶
(*b*) Used in connexion with venereal diseases schemes	130	—‖	Not av.
(*c*) Maternity sections used in connexion with maternity and child welfare schemes	26	279	
(3) Maternity hospitals (not including maternity sections in general hospitals)	64	1337	£114,000§
(4) Babies' hospitals	14	347	

‖ Available beds used as and when required. ¶ Including expenditure of the Welsh National Memorial Association on sanatoria and hospitals.

Not av. = Not available.

The figures under the above headings as to numbers of hospitals and beds are exclusive of accommodation in homes for unmarried mothers and their babies, observation wards in connexion with maternity and child welfare centres, and convalescent homes. Those under *b* (2) (*c*) are exclusive of accommodation used by local authorities in general hospitals for special or complicated maternity cases, as regards which figures are not available.

(*c*) *Institutions formerly provided by Poor-law Authorities.*

	Number.	Beds.	Expend. 1928–29.‡
(1) Institutions wholly for the sick, exclusive of institutions for mental cases	73	40,000	£4,316,000
(2) General institutions (with a total accommodation of some 188,000)	652	83,000(*a*)	£8,880,000(*b*)

(*a*) Beds in infirm and sick wards.
(*b*) Total expenditure on general institutions.

Cancer among Aniline Factory Workers.

Mr. PHILIP OLIVER asked the Home Secretary whether he was now in a position to report on the investigation being carried out by the London Cancer Hospital, with the assistance of the medical inspectorate of the factory department, into the incidence of the disease of cancer of the bladder among workers in aniline factories.—Mr. SHORT replied: This investigation has been continued, but I am unable to hazard any opinion as to when conclusive results may be expected. The hon. Member will appreciate that investigations into the causation of cancer in connexion with particular occupations are always very difficult, and that a special difficulty arises in the present investigation owing to the fact that the total number of fatalities from cancer of the bladder among aniline workers is quite small, and the collection of data, therefore, very laborious.

Manufacture of Dangerous Drugs.

Lieut.-Colonel FREMANTLE asked the Home Secretary when the report of the preliminary conference on the limitation of manufacture of dangerous drugs, recently held in this country, would be available to Members of Parliament.—Mr. SHORT replied: The report of this meeting of Government representatives from the manufacturing countries, which was one of the stages in the working out of the League scheme for the limitation of the manufacture of dangerous drugs, has been sent to the League, and, I am informed, is now in course of being printed. I am afraid I cannot say how soon copies will be available.

Mentally Defective Children.

Mr. DAY asked the President of the Board of Education the number of children in England and Wales between the ages of 5 and 16 who were ascertained by the education authorities to be mentally deficient; the number of these who were ascertained to be educable; the number who were ascertained to be ineducable; the number of such children who were attending schools, institutions, and other centres; and were there any statistics that would show the number receiving home training.—Sir CHARLES TREVELYAN replied: According to the latest returns available, 32,775 educable mentally defective children have been ascertained by local education authorities in England and Wales; of these, 28,598 were attending schools or other institutions. I am afraid that I am unable to give figures for ineducable children on a comparable basis, but I am informed that the names of 3274 children were notified to local authorities under the Mental Deficiency Acts during the year 1929, of whom 352 were sent to institutions.

Wrapping of Cheese in Tinfoil.

Sir CHARLES CAYZER asked the Minister of Health whether the warning conveyed in the annual report of the Ministry of Health as to the potential danger of the practice of wrapping cheeses in tinfoil was based on a report of an official analyst of the Ministry; and whether the samples examined were of British or of foreign origin.—Mr. GREENWOOD replied: The report quoted was that of a public analyst appointed by a local authority. The appointment of such an officer is subject to the approval of my department, who require to be satisfied as to the competence of the person appointed. I understand that some of the samples examined were British, and that some were imported.

Sir C. CAYZER: Does not the right hon. gentleman consider that a grave warning of this kind based on such slender evidence is calculated to do a great deal of harm to an important industry?

Mr. GREENWOOD: I do not accept the hon. Member's suggestion that there is slender evidence. A distinguished public analyst has said that in certain cases food was contaminated.

Infant Mortality.

Lieut.-Colonel FREMANTLE asked the Minister of Health the main reason for the increase in infant mortality in England and Wales in the years 1924 and 1929 respectively.—Mr. GREENWOOD replied: I am advised that the increase in 1924 was mainly due to an epidemic of influenza, and in 1929 to a similar epidemic coupled with an epidemic of whooping-cough.

TUESDAY, DEC. 9TH.

Education of Mental Defectives in Scotland.

Mr. TRAIN asked the Secretary of State for Scotland how many educable mental defectives in Scotland were receiving suitable education; what were the size and number of the classes; and what was the total expenditure.—Mr. JOHNSTON (Under-Secretary for Scotland) replied: The number of educable mentally defective children between 5 and 16 years of age receiving instruction in special schools, classes and residential institutions in Scotland is 3938. I am unable to state the precise number of the classes, but the number of children in a class is limited to 20. The statistical information available does not enable me to separate the expenditure on such instruction from the other expenditure of the education authorities.

X Ray Examination and Tuberculosis.

Dr. HASTINGS asked the Minister of Health the proportion of cases treated in dispensaries for the prevention of tuberculosis in which the diagnosis of pulmonary tuberculosis was confirmed by X ray examination.—Mr. GREENWOOD replied: The number of X ray examinations made in 1929 for every 100 new cases and contacts who were examined in tuberculosis dispensaries in England and Wales was slightly over 25. I have no information as to how many of these examinations resulted in the confirmation of a diagnosis.

Dr. HASTINGS asked the Minister of Health to wh extent facilities for the X ray examination of the ch were at the service of medical officers in charge of dispe saries for the prevention of tuberculosis.—Mr. GREENWO replied: Definite arrangements for X ray examination ha been made by 122 out of 140 tuberculosis authorities England and Wales, and by all the metropolitan borou councils. Other tuberculosis authorities have from time time provided X ray examinations for particular cases.

Relief of Sick Poor in Scotland.

Mr. KIRKWOOD asked the Secretary for Scotland whethe in view of the hardship now existing among the unemploy and sick poor in the face of the cold weather and the c of fuel, he would circularise the local authorities, aski them to increase the payments in respect of relief a particularly to make an increase during the Christmas a New Year weeks.—Mr. JOHNSTON replied: My right h friend is advised that any such recommendation as suggested in the question is outside his statutory powe Under the Scottish poor-law an authority is required grant needful assistance for the maintenance of healt But subject to this statutory limitation the Department Health have always agreed to a variation from the approv dietary in poor-houses at Christmas or the New Year.

Small-pox and Vaccination.

Mr. GROVES asked the Minister of Health whether had any reason to believe that the mild form of small-p which had been prevalent in certain districts of this count during the past eight years had shown any greater incide in those counties in which vaccination had been larg neglected as compared with those counties in which t practice had been more largely observed; and, if so, wo he supply statistical data in support of his view.—M GREENWOOD replied: I have no specific evidence that t incidence in any area of the type of small-pox at pres prevalent in this country bears any close relation to t percentage of infants vaccinated in that area. The in dence of the disease is, however, almost entirely limited unvaccinated persons or persons who have not been succe fully vaccinated within recent years.

Post-vaccinal Encephalitis.

Mr. GROVES asked the Minister of Health how ma cases of post-vaccinal encephalitis were brought to t notice of his department during the 12 months Oct. 1 1929, to Sept. 30th, 1930; how many proved fatal; a which of the cases, if any, were vaccinated with Gove ment lymph.—Mr. GREENWOOD replied: Fourteen cases which symptoms suggestive of disease of the central nervo system following within a month of vaccination have be brought to the notice of my Department as having occur during the 12 months ended Sept. 30th, 1930. I am advis that eight of these cases, four of which proved fatal, m be regarded as cases of post-vaccinal encephalitis. Of the eight cases, seven were vaccinated with Government lym and in one case there is no information as to the lym used.

The Schick Test.

Mr. FREEMAN asked the Minister of Health whether had information regarding the towns in which Schi testing and diphtheria immunisation were being practise and whether he could state the number of children in th towns that had been Schick tested and had received o two, or three immunisation inoculations for each ye separately.—Mr. GREENWOOD replied: I have sanction the provision of facilities for Schick testing and immunis tion against diphtheria in 38 districts in England and t in Wales, and I have information that these facilities a also provided in other areas. The information asked i in the second part of the question is not available.

Chemical Warfare Research.

Mr. R. S. YOUNG asked the Secretary for War if he co give the total number of the staff of the chemical warf department, and give the figures for 1920, 1925, and 19 respectively.—Mr. T. SHAW replied: The total number staff on the approved establishment of the chemical warf research department on April 1st of the respective ye is given below: 1920, 410; 1925, 480; 1929, 535; 19 553. The figures for 1920 exclude the staff of the Reseal Establishment, Sutton Oak, as in 1920 that establishm was under the Ministry of Munitions and figures are n available.

Mr. SINKINSON asked the Secretary for War how ma horses had actually been killed by poison-gas experime at Porton each year since the cessation of the great war Mr. T. SHAW replied: None, Sir.

MEDICAL SERVICE PROBLEMS IN AMERICA.

(BY A SPECIAL CORRESPONDENT.)

For some time past in America, more perhaps than in ost countries, public attention has been increasingly ected to the great question of the promotion of the alth of the people. In the press health topics ve considerable "news value"; health talks form opular feature in radio programmes, and there is ce in the statement that is sometimes made that erica has become "health conscious." Prominent ong the problems that are now being most widely cussed is that of securing at a moderate cost an equate provision of medical services to the entire pulation; and in the issue of the *Ohio State Medical urnal* of Sept. 30th there is a thoughtful and minating discussion of this problem by Dr. Willard Rappleye, the Director of Study of the Commission Medical Education, whose report on "Medical ucation in Europe" was reviewed not long ago our columns.[1]

EXPENDITURE ON MEDICAL CARE.

Dr. Rappleye begins by giving a remarkable imate of the direct expenditure on medical care in United States, which he takes to be rather more n 2 per cent. of the annual national income. His ures are as follows:—

	In millions of dollars.		Per family. Dollars.
Patent medicines and drugs	700	.....	25.00
Physicians	650	.....	24.00
Hospitals (civil)	380	.....	15.00
Nursing (all forms)	200	.....	8.00
Dentists	150	.....	6.00
Non-medical practitioners	50	.....	2.00
Total	2130	.....	80.00

The costs are contrasted with other forms of ional expenditure, namely:—

	In millions of dollars.		Per family. Dollars.
Passenger automobiles	4,000	.....	150.00
Tobacco	1,800	.....	67.00
Candy	1,000	.....	37.00
Gasoline (non-commercial)	1,000	.....	37.00
Movies, entertainment	930	.....	35.00
Soft drinks, ice-cream, gum	910	.....	34.00
Jewellery and furs	780	.....	29.00
Radios and musical instruments	440	.....	16.00
Sporting goods, toys, games	430	.....	16.00
Perfumes, cosmetics, toilet soap	410	.....	15.00
Total	11,700	.....	436.00

hese figures would appear to show that the erican people spend far less on doctors than on ly, and twice as much on perfumes, cosmetics, and t soap as on nursing; and they support Dr. pleye's suggestion that the obstacles in the way roviding complete medical services for the popula- lie not so much in economic facts as in the culty of devising a plan of medical provision that ld meet with general acceptance. Given such an, the funds necessary for its operation could be d.

NATIONAL INSURANCE.

ne consideration of the question naturally leads to examination of the various schemes of national rance against sickness that have been adopted in ope; but these do not meet with favour in America. the doctors State sickness insurance is regarded measure of "State medicine," to which the American medical profession is strongly opposed. To the ordinary citizen it savours of "paternalistic" government, and "paternalism" is held to be out of harmony with the American philosophy of life, although to the European observer the institution of prohibition on a national scale seems inconsistent with this view. The present indications certainly seem to suggest that it is not by the adoption of national health insurance based on European methods of compulsory insurance that the solution of the American problems will be attempted.

Moreover, State sickness insurance as we know it in Europe is limited to the wage-earning class and to the small-salaried employees, while the problem to be faced extends over a considerably wider area. Between the insured persons on the one hand, and those members of the community who are fortunate enough to be in a position to pay for all the medical services necessary for complete treatment on the other, there is a large class of potential patients who, while able to pay an ordinary doctor's bill, cannot afford the expenses of a major operation or of a protracted illness. To such persons the economic effects of severe sickness may be devastating; and the cost to them of adequate treatment tends continually to increase with the modern development of specialism and of the increasing recognition of the importance of team work as a condition of the successful attack upon disease. For the great majority of the community sufficient provision against sickness cannot be made by individual effort, and it would seem that some form of spreading the risk by communal action must be found.

VARIOUS EXPEDIENTS.

Various suggestions have been put forward for overcoming the difficulties inherent in the problem as it is now viewed in America, and various expedients are being adopted. There has been a great increase in the provision of hospitals and clinics. Many industries are establishing comprehensive medical services, some on a local insurance basis; and by some students of the problem it is thought that developments on these lines hold out the most likely prospects of successful results. There has been a rapid expansion of the "community chest" movement, this term being used to denote a scheme of voluntary taxation for the purpose, inter alia, of providing medical services. Dr. Rappleye states that over 350 American cities now have "community chests," and that in the year 1929 more than $50,000,000 was raised by them for various forms of social and medical relief. Progress has recently been made, especially in the Middle West, in what is known as "group practice"—i.e., the voluntary combination of a number of doctors, generally from 10 to 20—to offer a more or less complete medical service. Some groups have even provided a hospital for the treatment of their patients.

Dr. Rappleye suggests that in the solution of the problem it is up to the medical profession to take a prominent part, and he indicates various directions in which effort may most usefully be made. One lies in the devotion of increased attention to the preventive side of medical work—the making of preventive medicine an integral part of medical practice. Another is the more economical use of specialist services. He estimates that between 80 and 90 per cent. of medical needs can be met by adequately trained general practitioners; and he contends that the selection of cases for specialist advise should be made by the practitioner and not by the patient, and that the profession should devise means to furnish the public with some guarantee that those who claim

[1] THE LANCET, 1930, i., 1412; and *ii.*, 141.

to be specialists are, in fact, expert in their particular fields of practice. Another element in the solution of the problem is the systematic development of post-graduate study.

Dr. Rappleye concludes by laying stress upon the importance of leadership in the medical profession. "What we need," he says, "is a constructive and sustained programme directed and supported by t best brains of the medical profession, which will a to provide, control, and retain leadership in heal matters, and in the programme of medical servic through proper organisation of the profession, sou schemes of medical and post-graduate education, a wise constructive policy and publicity."

MEDICAL NEWS

University of Cambridge.

On Dec. 5th the following degrees were conferred :—

M.D.—W. H. Craib.

M.B. & B.Chir.—R. W. L. May, A. R. Banham, R. M. Bolam, and Stuart McDonald.

The Raymond Horton-Smith prize for 1929–30 has been awarded to Dr. P. M. D'A. Hart.

University of Bristol.

At recent examinations the following candidates were successful :—

M.D.—T A. Brand.

FINAL EXAMINATION FOR M.B. AND CH.B.

Part I. (including Forensic Medicine and Toxicology).—G. T. Bevir, R. N. O'D. Burns, R. G. C. G. Carlson, A. McD. Davies, G. M. Evans, A. L. Eyre-Brook, F. E. Fletcher, J. D. Hughes, Harold James, John Ridgway, Frances N. Salisbury, O. E. L. Sampson, and J. P. P. Stock.

Part I.—J. R. Gibbs.

Section II (Group I.).—Eveline M. D. M. Collinson and Rowena M. Hickman.

FINAL EXAMINATION FOR L.D.S.—E. R. Carpenter.

University of Liverpool.

The Council have appointed Dr. H. J. Channon to the Johnston Chair of Biochemistry, vacated by the resignation of Prof. Ramsden. Dr. Channon, a former Beit Memorial Fellow, is at present in the department of Experimental Pathology and Cancer Research at the University of Leeds.

Dr. H. E. Annett, late professor of comparative pathology, has been appointed to the Samuel Turner Research Fellowship.—Mr. J. S. Collinge, L.D.S., has been appointed lecturer in Operative Dental Surgery in the place of Mr. H. W. P. Bennette, resigned.

Royal College of Physicians of Edinburgh.

At the annual meeting of the College on Dec. 4th Sir Norman Walker was re-elected President for the ensuing year. Dr. Robert A. Fleming, Dr. Robert Thin, Dr. William Fordyce, Dr. Edwin Bramwell, Dr. Edwin Matthew, and Dr. A. Fergus Hewat were elected members of Council, and Dr. Robert Thin was nominated vice-president. At an extraordinary meeting held at the close of the annual meeting Dr. John Orr and Dr. William Fordyce were elected representatives on the board of management of the Royal Infirmary. The College voted a sum of 1000 guineas to the Royal Infirmary, Edinburgh, in response to its bicentenary appeal.

Hunterian Society of London.

The next award of the Hunterian Society's medal will be made in 1932. The object of the award is to encourage individual effort among general practitioners in advancing the science and art of medicine. The competition is open to all general practitioners resident in Great Britain, Ireland, and the Channel Islands, whether Fellows of the society or not. The medal will be given for the best essay on some subject, chosen by the candidate, from the province of medicine, surgery, and midwifery. Essays must be received on or before Dec. 31st, 1931. The rules governing the award may be obtained on application to the hon. secretaries: Dr. D. C. Norris, 14, City-road, London, E.C.; and Mr. Andrew McAllister, 79, Wimpole-street, W. 1.

Medical Benevolent Fund Guild.

The Father Christmas Branch of the Guild, over which Lady Tweedy presides, is issuing a special appeal to enable the Guild to make Christmas gifts to annuitants and necessitous grantees, thus making a small attempt to cheer the lot of those who have fallen on evil times. A similar effort has been made in past years but the needs are always greater than the money received, and a warning to this effect will be timely. Many doctors, their wives and their children subscribe to the Branch, and give pleasure to a large number by so doing, but more 5*s.* and 3*s.* subscriptions are needed, as well as gifts in kind. We call attention to the Branch in the hope that the distributors may receive promptly some assistance in their labour of kindness. The honorary treasurer is Miss Swinford Edwards, 68, Grosvenor-street, London, W. 1.

King George Hospital, Ilford.

On Thursday last week, Prince George presided at t "foundation dinner" of this hospital at Carpenters' Ha and at the end it was announced that the building fu amounted to £107,000.

Hospital for Sick Children.

Sir James Barrie last week took the chair at a festi dinner at the Guildhall in support of the appeal for t reconstruction of the new Hospital for Sick Children Great Ormond-street. After the dinner donations amounti to £40,568 were announced.

London (Royal Free Hospital) School of Medici for Women: Annual Dinner.

Former students of the school, as usual, showed th confidence in the successful organisation of this ann function by bringing many guests to dine, to listen to sh apt speeches, and then to dance. A party of more than 4 assembled punctually and stayed late, though, or possil because, the formal proceedings were soon complet After the loyal toasts, Mr. St. John Ervine, in proposi the School and Hospital, confessed to two errors, b of which that evening had done much to remove: an infant fear of medical students and an entire misconception the educated woman. His claim that the theatri profession had the honour of being the pioneer of equal between men and women was conceded with applau He sympathised with the practising doctor in his task tinkering up such an inconvenient machine for its purp as the human body, and expressed a flattering convict that any good doctor, assisted by a competent engine would have made a better job of it. Speaking of the l to the school of Dame Mary Scharlieb, Mr. Ervine recal her unusual qualities, which caused her to inspire in t young as much affection for herself as she felt for the

Mr. Malcolm Henderson, the chairman, responding to t toast, announced that the association between the Ro Free Hospital and the London School of Medicine Women had recently been cemented by an agreem extending over the next 50 years. The entry of stude to the school had, in recent times, not only been maintain but had actually increased. During his long connexion wi the school the buildings had had to be extended to dou their size. He felt honoured to have been privileged work with the women to whose courage and wisdom t development had been due.

Mr. L. E. C. Norbury, F.R.C.S., in terms of cord welcome, proposed the guests. These included, besid Mr. Ervine, Lord Moynihan, P.R.C.S., Mrs. Kinnell, t Chairman of the Appeal Committee, Miss Jebb, the Princi of Bedford College, and the Editors of the *British Medi Journal* and *The Lancet*.

Mrs. Kinnell, in reply, said that it was always a pleasure her to be associated with the school and the hospital eith in work or in play; they brought to all their enterpri a stimulating vigour, kindliness, helpfulness, and se helpfulness. Some weeks ago, Mr. Baldwin, when speaki at the Girton College Extension Dinner, had noted t disabilities under which the Women's Colleges did th work in the general life of the University. On the mater side he regretted for them the lack of beautiful collegi buildings, old chapels, and rich endowments; but he regrett also on the immaterial side the lack of the great traditi which it is the privilege of the sons and brothers of the r to inherit and to maintain. Mrs. Kinnell held t there was something better in life than inheriting a gr tradition, and that was creating one.

Lord Moynihan spoke of the special place of women medicine; he welcomed the increasing number of wom taking up laboratory work, for which he deemed th exceptionally well fitted.

The last toast, that of the chairman, was proposed by M Waller, B.Sc. She spoke of the great services rendered the school over a period of 35 years by the firm of solicit to which Mr. Henderson belonged. He had inherited fr his father a keen interest in its progress and had alw been one of its most staunch friends and supporters.

xtension of St. Bartholomew's Hospital, Rochester.

The Rev. J. Bailey, the Prior, recently dedicated the new t-patients' department, which has cost £20,000. The remony marked the completion of the first part of a mprehensive scheme of extension, the cost of which will ceed £100,000. The new buildings include an operating eatre for casualties and minor cases.

n Indian Hospital for London.

The Indian Medical Association (Great Britain) is pro- ɔting a scheme for the establishment of an Indian hospital London, with the support of a number of delegates to the ɔund-Table Conference and Indian medical men in England. is proposed that the hospital should be started with beds. Indian post-graduates would be provided with use appointments, facilities would be given to Indian ctors for research and specialisation, and a centre of ining as nurses to Indian women created. The initial pital cost is estimated at £12,500, and the annual expenses the first few years at about £4500.

Appointments

AMINGS, R. E., L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon, Nuneaton General Hospital.

OYD, R., L.R.C.P. Lond., M.R.C.S., Certifying Surgeon under the Factory and Workshop Acts for Southminster, Essex.

FKIN, D. M., L.R.C.P. Lond., M.R.C.S., House Surgeon, Birmingham Children's Hospital.

EKIE, M., M.B., Ch.B. Manch., Asst. Medical Officer of Health, Bromley, Kent.

EWART, W. A. McEWAN, L.R.C.P., F.R.C.S. Edin., L.R.F.P.S. Glasg., County Medical Officer for Essex.

stminster Hospital: DAVIES, E. T., L.R.C.P. Lond., M.R.C.S., and STEWART, J. G., L.R.C.P. Lond., M.R.C.S., Resident House Surgeons. GOULDENBACH, L. M. A., L.R.C.P. Lond., M.R.C.S., and BUCK, G. H., L.R.C.P. Lond., M.R.C.S., Resident House Physicians.

Vacancies

For further information refer to the advertisement columns.

rdeen Royal Infirmary.—Hon. Jun. Ophth. Surgeon.
Saints' Hospital for Genito-Urinary Diseases, 91, Finchley-road.—H.S. At rate of £150.
kenhead General Hospital.—Sen. H.S. £150.
dford Royal Infirmary.—Hon. Surg. Also Hon. Asst. Surg.
ghton, Royal Sussex County Hospital.—Cas. H.S. £120.
stol, Hortham Colony for Mental Defectives.—Med. Supt. £700.
stol General Hospital.—H.P.'s, H.S.'s, Res. Obstet. O. Each at rate of £80. Also Cas. H.S. At rate of £100.
rnley, Victoria Hospital.—Two H.S.'s. Each at rate of £150.
ry Infirmary, Lancashire.—Third H.S. At rate of £150.
rlisle, Cumberland, and Westmorland Mental Hospital, Garlands.—Jun. Asst. M.O. £350.
nnaught Hospital, Orford-road, Walthamstow, E.—Sen. Res. H.S. At rate of £150.
ydon General Hospital.—Hon. Physician to Children's Dept.
byshire Royal Infirmary.—Non.-Res. Radiologist. £100.
by County Mental Hospital, Mickleover.—Jun. Asst. M.O. £350.
blin, Mercer's Hospital.—Hon. Asst. Visiting Surgeon. Also Hon. Jun. Anæsthetist.
lley, Guest Hospital.—H.S. £170.
rham County Hospital.—Two Res. H.S.'s. Each £160.
ex County Council.—Asst. County M.O.H. £500–£600.

rpool Sanatorium, Delamere Forest, Frodsham.—Asst. Med. Supt. £250.
nchester. Ancoats Hospital.—H.S. for General Surgery, &c. At rate of £100.
nchester Royal Infirmary.—Asst. Res. Surg. O. At rate of £150.
nchester Royal Infirmary, Central Branch, Roby-street.—H.S. £100.
ropolitan Hospital, Kingsland-road, E.—Asst. M.O. to X Ray Dept.
National Hospital, Queen-square.—Hon. Surg. Asst. Also Hon. Asst. Surg.
Newcastle-upon-Tyne, Hospital for Sick Children.—Jun. H.S. At rate of £100.
Pontefract General Infirmary.—H.S. £150.
Poplar Hospital for Accidents, East India Dock-road, E.—Sen. Res. O., &c. £200 plus £75.
Reading, Royal Berkshire Hospital.—H.P., H.S., and Cas O. All at rate of £150.
Royal Waterloo Hospital for Children and Women.—Res. H.S. At rate of £100.
St. Mark's Hospital for Cancer, Fistula, and other Diseases of the Rectum, City-road, E.C.—H.S. At rate of £75.
St. Peter's Hospital for Stone, &c., Covent Garden, W.C.—Clin. Assts.
Salford Royal Hospital.—Cas. H.S. At rate of £125.
Sheffield Royal Infirmary.—Ophth. H.S. £80–£100, H.P., H.S., Asst. Aural and Ophth. H.S. Also Asst. Cas. O. All at rate of £80.
South London Hospital for Women, South Side, Clapham, S.W.—Three H.S.'s. Each at rate of £100. Also Asst. S. to Ear, Nose, and Throat Dept.
South Shields, Harton Hospital.—X Ray and U.V.R. Operator. £250.
Southampton, Royal South Hants and Southampton Hospital.—Sen. H.S. £225. Also H.P., and Two Asst. H.S.'s. Each at rate of £180.
Southampton, Royal Eye Hospital.—H.S. £150.
Sutton, Surrey, Sutton and Cheam Hospital.—Hon. Acting Surg.
Swansea County Borough.—Asst. M.O. £600.
Swansea General and Eye Hospital.—H.P. £150.
Torquay, Torbay Hospital.—H.P. £175.
Warwick, King Edward VII. Memorial Sanatorium, Hertford Hill.—Sen. Asst. M.O. £275.
Walsall General Hospital.—H.S. At rate of £150.
Watford, Herts, Peace Memorial Hospital.—Res. Surg. O. At rate of £150.
West African Medical Service.—Medical Officers.
Weston-Super-Mare General Hospital.—Res. H.S. At rate of £150.
Wigan Royal Infirmary.—H.S. At rate of £150.

The Chief Inspector of Factories announces a vacant appointment for a Certifying Factory Surgeon at Hackney (London).

Births, Marriages, and Deaths

BIRTHS.

CORMACK.—At the Dufferin Hospital, Rangoon, on Friday, Nov. 7th, to Dorothy, wife of Lt.-Col. H. S. Cormack, I.M.S.—a son.

HAYCRAFT.—On Dec. 4th, at Cathedral-road, Cardiff, the wife of John Berry Haycraft, *M.C.*, F.R.C.S., of a daughter.

LYDON.—On Dec. 3rd, at Galway House, Shire Green, Sheffield, to Helen Anderson, M.B., Ch.B., wife of F. L. Lydon, M.B., Ch.B.—a son.

MADGWICK.—On Dec. 2nd, to Adèle Hope, M.B., B.S., the wife of John R. A. Madgwick, M.B., B.S.—a son.

WELLS.—On Dec. 5th, at Barrington Hall, Cambridge, the wife of Dr. Arthur Q. Wells, of a daughter.

WHITEHEAD.—On Dec. 1st, at York-mansions, S.W., the wife of Major N. T. Whitehead, R.A.M.C., of a daughter.

WILSON.—On Nov. 22nd, at Carisbrooke, Plymouth, to Vera, wife of Edric F. Wilson, F.R.C.S. Eng.—a daughter.

MARRIAGES.

GRAY—GADSDON.—On Dec. 2nd, at Colchester, George Milne Gray, F.R.C.S., to Philippa Jeanne, daughter of Mr. and Mrs. H. P. Gadsdon, of Clacton.

LOVE—LAMBERT.—On Nov. 29th, at St. Mary's, Snettisham, King's Lynn, William Griffith Love, M.B., of Woodville, Burton-on-Trent, to Peggy, eldest daughter of Ernest W. Lambert, of Sutton Lea, Snettisham.

WILLIS—WHITTET.—On Dec. 4th, at Braid Church, Edinburgh, William Elliott Willis, M.B., Ch.B., to Mary Margaret, daughter of the late H. F. Whittet, solicitor, and Mrs. Whittet, Comiston-road, Edinburgh.

DEATHS.

BAILY.—On Dec. 4th, at La Forêt, Cannes, A.M., Edwin Baily, M.B., C.M., M.B.E., late of Oban, Argyll.

BENNETT.—On Dec. 3rd, at Regent-road, Leicester, Frederick William Bennett, M.D., B.Sc., aged 70.

BRIMACOMBE.—On Dec. 5th, at Tunbridge Wells, Richard William Brimacombe, T.D., M.D., late Lieut.-Colonel, R.A.M.C.

FOWLER.—On Dec. 1st, at College-road, Hampstead, N.W., Trevor Hayman Fowler, M.R.C.S., L.R.C.P., late Captain, R.A.M.C.

HAMMOND.—On Dec. 1st, John Balding Abbott Hammond, M.B. Lond., of Cleveland-gardens, W., and formerly of Shanklin, I.O.W., aged 54.

HERDMAN.—On Dec. 6th, very suddenly, Ronald Tydd Herdman, M.D.

KILNER.—On Dec. 1st, at the Old Mill House, Bury St. Edmunds, Charles Scott Kilner, M.B.E., M.B., B.Ch., D.P.H., J.P.

PRITCHARD.—On Nov. 27th, suddenly, at Heathfield, Dewsbury, Joseph James Gawler Pritchard, M.R.C.S., L.R.C.P., aged 66 years.

SECCOMBE.—On Dec. 4th, at Chester-place, Regent's Park, N.W., Philip John Ambrose Seccombe, M.B., aged 61.

TODD.—On Monday, Dec. 1st, 1930, William Alexander Todd, M.B., Ch.B., Medical Superintendent of Killingbeck Sanatorium.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices o Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

A HISTORY OF MEDICINE IN MASSACHUSETTS.

IT is no easy task to compress 300 years of medical history into less than 200 pages, and to make a readable book. Dr. Viets deserves congratulation, for his book [1] is really interesting and should make a wide appeal. A brief introduction shows that the chief element in medicine to be transferred to America, in 1620, was the widespread belief in Galenic principles, tinged with the then heterodox views of Paracelsus, Vesalius, and the giants of the Renaissance. Two men with medical knowledge, Deacon Dr. Samuel Fuller and Giles Heale, a barber-surgeon, were passengers on the *Mayflower*. Heale returned in that ship in 1621. Fuller stayed in New England, and died of small-pox in 1638. His third wife practised as a midwife. The early history of medicine in America is largely bound up with theology. Governor Winthrop found time to practise physic in addition to his other activities; especially interesting is the transcript of the letter written by him in 1652, dealing with a case of paralysis in a child. Thomas Thacher printed, in 1677, a broadsheet, epitomising Sydenham's views on the small-pox. John Clark, the first regular medical man in New England, arrived in 1638, and was the progenitor of a long line of physicians, seven in number and all named John, the last of whom died in 1805.

It is interesting to note that attempts at prevention were quickly to the fore, a strict quarantine being established at Boston by 1648 over all vessels arriving at the port. Conditions of life in this early colonial period were very hard, as were also conditions of practice if we may judge from the story of a barber-surgeon, named Dinely, who, while journeying to Roxbury to pull a tooth, was lost in a snow-drift. It was some days before his body was found and his widow, in her grief, fell into premature labour, and on the baby being born, insisted on saddling it with the name of Fathergone Dinely.

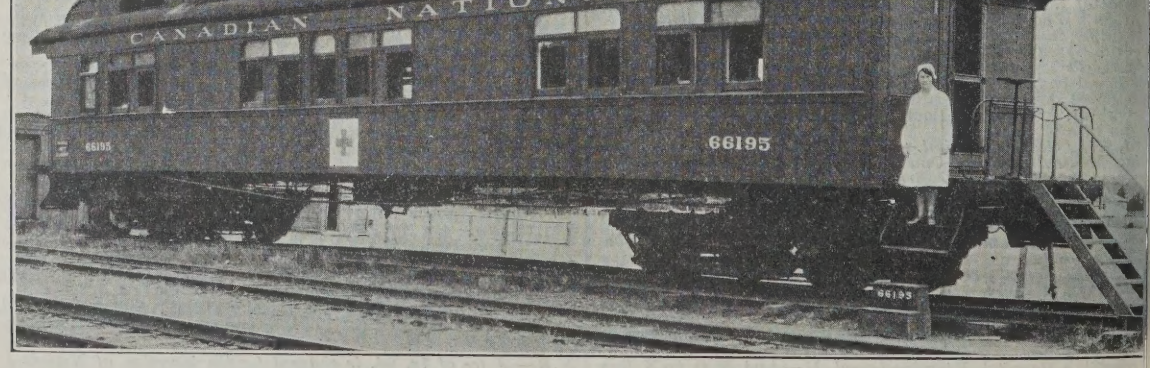
The chapter on the colonial period is followed by one on the first 75 years of the eighteenth century, culminating with the war of Independence. Boylston's inoculations in and after 1721 are the most interesting part of his chapter, and it contains goo accounts of Douglass and Dr. James Lloyd. T war of Independence coincided with the rise of t Warrens and the part played in the revolution the medical fraternity of Boston is described. Th we have accounts of the foundation of t Massachusetts General Hospital and Medical Socie and the rise of Harvard. Biographies of Oliv Wendell Holmes, Jackson, Bigelow, and other pionee lead up to an excellent chapter on Morton and t first administration of ether for a major surgic operation, an illustration of which forms the front piece. Other pioneer American anæsthetists, su as Wells and Long, are here rescued from oblivio and we are glad to see that although the name of t first patient is not included in the frontispiece, finds a place in the text; it was Gilbert Abbott, name surely worthy of remembrance. A bri sketch of modern developments concludes a we written and fascinating book.

[1] A Brief History of Medicine in Massachusetts. By Henry R. Viets, M.D. With illustrations. Boston and New York: Houghton Mifflin Company. 1930. Pp. 194. $4.

TRAVELLING HOSPITALS IN CANADA.

THE provision of adequate medical attenti in the more remote districts of Canada has been pressing problem ever since pioneer days. There w a time before the coming of the railway when t farmer and his wife on the frontier of the west had rely on their own native ingenuity and comm sense in the treatment of household ills. Abo three-quarters of the population of Saskatchew is still rural, and not a small proportion lives in ou lying districts to which the problem of bringi health services is difficult. Recently the provinci Government made provision whereby communiti could obtain the services of doctors under a coöperati plan. One scheme empowers a rural municipali to make a grant to a medical practitioner as inducement to him to take up his residence a practise his profession in the community, a gra of money up to $1500 being made to him for th purpose. The other plan is that which makes possible for rural municipalities, by vote of t residents of the area, to engage a full-time practition at a salary not exceeding $5000 yearly. In th case the doctor acts as the community doctor, givi free medical service to all ratepayers and their familie Thirteen Saskatchewan municipalities are trying o the first scheme and 19 districts the second schem

FIG. 1.



The Red Cross car of the Canadian National Railways stationed at Fort Frances, Ontario.

he ratepayers in the atter case paying a tax of something like $3.85 per quarter section of 160 acres. In one or other of these ways there are now few communities which have no doctor within reasonable reach in ase of emergency.

Many districts, however, till lack adequate facilties for the treatment of more difficult cases and or the isolation of patients uffering from contagion, r for the spreading mongst the population enerally of elementary nstruction in first-aid. t is to fulfil this function hat the Canadian ational Railways are lacing in service on their nes three new hospital nd first-aid cars. It is he intention of the anagement that these rs shall be used where spital accommodation limited and where a nowledge of first-aid is ecially desirable. They ill also be used in disters, such as train wrecks nd mine explosions, where speed in the provision of edical assistance is essential. The cars will be in harge of an experienced medical practitioner and will e hauled from place to place as occasion demands. In ral communities lectures will be conducted in the dy of the car, illustrated by means of charts and oving pictures, on the subject of first-aid and mentary medical science.

The cars themselves (Fig. 1) are virtually travelling spitals. They are 71 feet long and divided into sections, including a locker room, a lecture room, d operating theatre, bathroom, kitchen, and sleepg quarters for the official in charge. The equipment cludes a steel operating table, instrument cabinet, dicine chest, and racks with all kinds of splints. e lecture room (Fig. 2) has a blackboard and various rts and, when required, may be transformed into a convalescent or isolation ward (Fig. 3). The living accommodation for the attendant is equipped with lockers and a small kitchenette. The bathroom in block tile has a shower. Plentiful provision of hot water is ensured by a 200-gallon tank placed on top of the car, connected with a heater. Three independent systems are used for lighting. The electric lamps may be lit by current supplied either from the car batteries or from an outside source while the car is standing in a siding; should both these fail, oil lamps present a third alternative.

The first car is already in service and the others will be completed shortly.

THE RELATION OF REASON TO LIFE.

WITH his accustomed literary skill and dialectic invective, Dr. Schiller has again attacked the problem of the relation of reason to life as an activity.[1] Those who are familiar with his writings on logic in relation to humanism, belief, and formal logic, will find this study familiar, and, unfortunately, without any substantial new matter. The author's thesis is that formal logic strips actuality of its vital links and robs it of its very meaning as a fabric of relations that exist in and for activity. He tries to liberate logic from its thraldom to words and formulæ, and therefore attacks, in the main, absolutism. The most important chapters for any person interested in scientific method are those on Meaning and Formal Theories of Judgment. The author seems, however, to have ignored the advances in the subject of Meaning made by Ogden and Richards. Vaininger is mentioned only once. The book may cause irritation because of its omissions, but is certainly entertaining.

[1] Logic for Use. By F. C. S. Schiller, Fellow of Corpus Christi College, Oxford, and Fellow of the British Academy. London: G. Bell and Sons Ltd. 1929. Pp. 455. 16s.

CONGRESS OF RADIOLOGY.

EXHIBITION AND DINNER.

THE annual congress and exhibition of the British Institute of Radiology (incorporated with the Röntgen Society), held at the Central Hall, Westminster, from Dec. 3rd to 5th, was attended by radiologists from all over the country, with a sprinkling of visitors from the continent. The congress centred round an exhibition of X ray and other apparatus, even a casual inspection of which was enough to show that English manufacturers are well up to date and that their apparatus compares favourably with that of foreign manufacture. There were no striking novelties. Contrary to American practice, which so far has adhered strictly to mechanical rectification, valve rectification here holds the field with the exception of one exhibit. Where all apparatus is so good it is invidious to single out any for special mention; the needs of the radiologist are still varied, and apparatus that meets the need of one will not necessarily be ideal for another. The protective measures in all are of high standard, fully up to that laid down by the Protection Committee, and the exhibition is one that does great credit to the British manufacturers.

The papers presented at the congress were few in number but of exceptional interest. In the technical section was described the new tube that has two focal spots, one for ordinary radiography, the other of large area for use with heavy current in order to obtain rapid clear exposures at long distances. In the medical session Dr. H. A. Harris related his conception of the growth of bone and of arrest due to illness, and Dr. Donald Hunter gave an account of his work on the influence of thyroid and parathyroid on bone, particularly osteitis fibrosa. The Mackenzie Davidson Memorial Lecture was delivered by Prof. G. P. Thomson, F.R.S., on Some Recent Experiments on Cathode Rays; the Silvanus Thompson Memorial Lecture by Dr. A. E. Barclay on the Danger of Specialisation is printed substantially at the front of this issue. It is a good practice for a physicist to give the memorial lecture to radiologists, and vice versa.

The annual dinner held on Dec. 5th at the Trocadero Restaurant was attended by about 140 guests. The President of the Congress, Major C. E. S. Phillips, occupied the chair and Mr. Cuthbert Andrews, in proposing "The Institute," remarked that it was as natural to couple the President's name with the Institute as to link Adam & Eve, David & Jonathan, Burke & Hare, and in more modern times Elephant & Castle. He made a strong appeal for the linking to the Institute of the several independent radiographic societies which were being formed in various provincial centres, and suggested that this could be done primarily by making the *British Journal of Radiology* the official organ for all radiological societies, and so ensuring a comprehensive and accessible record of British radiology. The toast of "The Guests" was proposed by Prof. Woodburn Morison and was responded to by Sir Cuthbert Wallace, Mr. C. C. Paterson, and Dr. Watts Eden. In the intervals of the dinner the Westminster Glee Singers sang.

NEW PREPARATIONS.

(1) EXHEPA, (2) GASTROSIC LEO (Messrs. C. L. Bencard, Ltd., 184, Wardour-street, London).—(1) Exhepa, as its name indicates, is an extract of liver; the glands are selected and fresh and the preparation claims to contain unimpaired the active substances found to be beneficial in pernicious anæmia. It is manufactured by the Danish Chemical Therapeutic Society in Copenhagen, in accordance with a method evolved in collaboration with the Danish Government Serum Institute, by whom the freshness of the glands and the special methods of extraction and desiccation are guaranteed. Exhepa is put up in glass vials, hermetically sealed, and packed in boxes of ten vials, each vial representing a dose equivalent to 4 oz. of fresh liver. For patients who find the characteristic smell and taste of liver disagreeable, the preparation is supplied in a more palatable form, with no alteration of therapeutic value or of price.

(2) From the same firm we have received samples of Gastrosic Leo manufactured from the freshly killed hog stomach. This preparation is also under the control of the Danish Government, and is recommended to the medical profession on the experience derived from tests in certain Danish hospitals as an auxiliary treatment along with liver extract.

NURSERY BISCUITS.

WE have received an assortment of Robb's nursery biscuits which are well known in homes and institutions as useful food for the aged, invalids, and infants from the age of 6 or 7 months. The venerable duration of their popularity makes it unnecessary to say more of these biscuits than that they continue to deserve it.

Medical Diary

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
TUESDAY, Dec. 16th.—5.30 P.M., GENERAL MEETING OF FELLOWS. Ballot for election to the Fellowship.
THURSDAY.—5 P.M., DERMATOLOGY. (Cases at 4 P.M. Cases: Dr. H. W. Barber, 1 and 2: Congenital Ichthyosiform Erythrodermia. 3. Psoriasis Associated with Rheumatoid Arthritis. Other cases will also be shown.
FRIDAY.—8.30 P.M., ELECTRO-THERAPEUTICS AND COMPARATIVE MEDICINE. Discussion: A Comparison of Radiological Problems in Man and Animals. Openers: Major A. A. Pryer, Dr. R. W. A. Salmond, Lieut.-Colonel E. Middleton Perry, and Dr. J. B. King, followed by Prof. J. McCunn, Dr. A. E. Barclay, Dr. J. P. Brailsford, Dr. A. Eidinow, and others.

HUNTERIAN SOCIETY.
MONDAY, Dec. 15th.—7.30 P.M. (at Simpson's Restaurant, 2 and 3, Bird-in-Hand-court, 77, Poultry, Cheapside). Dinner. 8.30 P.M., Dr. Remington Hobbs and Mr. M. Oldershaw open a discussion on Puerperal Infection.

CHELSEA CLINICAL SOCIETY.
TUESDAY, Dec. 16th.—7.30 P.M., Dinner Meeting at the Rembrandt Rooms, Thurloe-place, S.W. Sir Thomas Horder will open a discussion on the Treatment of Fibrositis.

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1, Upper Montague-street, W.C.
FRIDAY, Dec. 19th.—5 P.M., Mr. D. S. Rabagliati, F.R.C.V.S. and Sir W. Dalrymple-Champneys: Undulant Fever.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY, Dec. 15th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nose and Throat Clinics. Operations.
WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.
THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M. Medical, Surgical, Throat, and Ear Clinics. Operations.
FRIDAY.—10.30 A.M.: Ear, Nose, and Throat Clinics. 2.30 to 5 P.M.: Medical, Surgical, and Children's Disease Clinics. Operations.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark-hill, S.E.
THURSDAY, Dec. 18th.—9 P.M., Dr. J. A. Drake: Some Common Skin Diseases Illustrated by Epidiascope and Lantern.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, Dec. 16th.—5 P.M., Dr. S. E. Dore: Erythematous squamous Eruptions.
THURSDAY.—5 P.M., Dr. I. Muende: Pathology Demonstration.

CITY OF LONDON MATERNITY HOSPITAL, City-road, E.C.
THURSDAY, Dec. 18th.—5 P.M., Dr. H. Burt-White: Importance and Treatment of Hæmorrhage in Pregnancy.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.
FRIDAY, Dec. 19th.—4 P.M., Mr. W. A. Mill: Hoarseness.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.
TUESDAY, Dec. 16th.—3.15 P.M., Dr. Rubens Wade: Anæsthesia.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, Dec. 17th.—4 P.M., Prof. Edgar L. Collis: Prevention of Industrial Diseases.

ST. JOHN'S HOSPITAL, Morden-hill, Lewisham.
MONDAY, Dec. 15th.—4.30 P.M., Dr. John Gibbons: Cardiac Cases in Infancy and Childhood.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
TUESDAY, Dec. 16th.—4.15 P.M., Dr. E. B. Leech: Pericarditis and Adherent Pericardium.

ADDRESSES AND ORIGINAL ARTICLES

THE NEURO-MUSCULAR OBSTRUCTIONS OF THE GASTRO-INTESTINAL TRACT.*

BY A. JAMES WALTON, M.S., B.SC. LOND., F.R.C.S. ENG.,
SURGEON TO THE LONDON HOSPITAL.

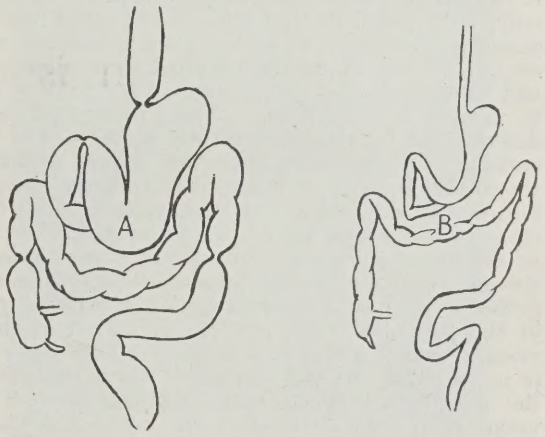
Mr. H. G. Wells, in one of his epic stories, makes his hero say: "This here progress it keeps on . . . you'd hardly think it *could* keep on." In no branch of knowledge is this more true than in that of medicine. In recent years progress has been so great that it is impossible for any one man to obtain a complete mastery of the whole subject, and, indeed, great difficulty is being experienced in arranging the curriculum so that the student can obtain a wide survey of the whole of medicine in the short time at his disposal. I believe, however, that we are even now on the brink of the discovery of a few basic facts which will tend to simplify medicine as a whole.

Already there is a tendency for certain diseases which have been regarded as distinct from one another to be grouped together as different manifestations of similar lesions. One of the most elusive and interesting of such groups is that concerned with the neuro-muscular mechanism of the gastro-intestinal tract. More and more conditions are being recognised as due to an abnormal action of this mechanism, so that they now form a large proportion of all abdominal lesions.

The forward passage of the intestinal contents is dependent in the normal state upon the presence of painless peristaltic waves, each of which consists of a ring of contraction preceded by a zone of relaxation; the whole passing down the wall of the gut. Although in many areas combined with other movements, these peristaltic waves are present from the commencement of the œsophagus to the termination of the pelvic colon, and are controlled by the vagus and sympathetic nerve fibres. In the œsophagus, as Kelly states, experimental work has shown that section of the vagi is followed by dilatation of the œsophagus, while stimulation of the peripheral end causes contraction of the whole tube. In the stomach the experimental results are less uniform, but Watanabe and McCrea show that the balance of evidence supports the view that stimulation of the vagus increases the excitability of the stomach and decreases the emptying time. Similar results are given by division of the sympathetic fibres, while their stimulation has the opposite effect. Hughson, on the other hand, showed that section of the vagus decreases the emptying time. In experiments on the intestines, Koehler finds that the vagal impulses excite peristalsis, and the sympathetic impulses diminish it. As Eppinger and Hiss have shown, two conditions may therefore be recognised: the vagotonic, which is shown by hypermotility and hypertonicity; and the sympatheticotonic, shown by atony and hypotonus.

In the case of the fixed sphincters the evidence is less clear. It would be expected that with increased peristalsis there would be relaxation of the sphincters, whether at the cardia, the pylorus, the ileo-cæcal valve, or the pelvi-rectal junction. Spasm of these sphincters would also be expected with inadequate action of the vagus or overaction of the sympathetic In a similar way, the failure of a peristaltic wave to pass on—that is, an area of spasm of the intestinal tube—would be expected with sympathetic overaction or vagus inhibition. Clinical evidence strongly supports this view, but the experimental findings are less definite. Thus, although Kelly states that section of the vagus is followed by failure of relaxation of the cardia and stimulation of the peripheral end by dilatation of this sphincter, Hughson found that after division of the vagal supply to the stomach it was impossible to produce reflex pylorospasm,

FIG. 1.



Diagrammatic representation of the gastro-intestinal tract: (A) with section of vagus or stimulation of sympathetic; (B) with stimulation of vagus or section of sympathetic.

and McCrea found that resection of the pyloric vagal branches produced a semipatulous condition of the pyloric sphincter. In spite of these somewhat divergent findings, the consensus of opinion to-day is that the vagal impulses are augmentor, and the sympathetic are inhibitory. (Fig. 1.)

The acceptance of these views will make it evident that there are three changes which may give rise to obstruction in some portion of the intestinal tract. These three are: (1) paralysis of both systems, or, as Koehler suggests, a balance at a lower level than normal; (2) relative paralysis of the vagus, or overaction of the sympathetic, for all impulses; (3) relative paralysis of the vagus, for those impulses which pass only to the sphincters.

Paralysis of Both Systems.

ACUTE DILATATION OF THE STOMACH AND ILEUS PARALYTICUS.

Ætiology and Pathology.—Both conditions may occur at any age or in either sex, but in my experience there is unquestionably a personal idiosyncrasy, so that certain patients have a tendency to develop paralytic dilatation of the stomach or intestines under a slighter provocation than that usually required. If there be any evidence of this congenital fault, an operation, and especially an abdominal operation, should only be undertaken after very careful preparation. There have occurred in my own practice several cases who have developed this serious complication after two separate operations.

* The Purvis Oration, delivered before the West Kent Medico-Chirurgical Society on Dec. 12th.

Rarely the symptoms may arise after over-distension of the viscera and as a sequel of acute disease. More commonly it is found as a result of operative treatment—the three most potent predisposing factors appearing to be the administration of an anæsthetic, rough handling of the stomach or intestines, and the presence of sepsis. Nevertheless, a number of cases had been reported where acute paralytic dilatation has followed operations other than those upon the intestines, and even where no anæsthetic has been administered.

The pathological changes are similar in both conditions. The stomach is greatly dilated, so that it fills nearly the whole of the abdomen. It is V-shaped, with an immensely dilated descending limb on the left, and a somewhat similar ascending limb on the right; the two limbs being separated by a sharp kink on the lesser curve. The wall of the stomach is so thin that it appears to be formed of one layer only, and is sufficiently transparent for the fluid or gaseous contents to be visible when the abdomen is opened. When the stomach is lifted up the dilatation and thinning is seen to pass beyond the pylorus and to involve the duodenum. Many cases have been described as terminating abruptly at the site of the crossing of the superior mesenteric vessels, and thus the condition has been regarded as an acute obstruction due to the pressure of these vessels. It is true that in a few cases a line of necrosis has been observed at the site of the vessels, but in my own experience this is rare, the dilatation gradually decreasing and fading away near the flexure or in the upper part of the jejunum. It is possible that even in those cases in which a line of necrosis has been observed it is secondary to the dilatation which compresses the gut against the vessels. Examination of the viscus from within will show the same evidence of dilatation with flattening of the normal mucosal folds, and general thinning. Areas of superficial ulceration and erosions are constant, and it is the loss of blood in small quantities from these areas that gives the brown or black colour to the vomit.

The pathological changes in the intestine in paralytic ileus are almost identical. There is the same enormous dilatation and thinning, with no evidence of any hypertrophy of the gut wall, the same absence of any mechanical obstruction, and yet the same failure of the intestinal contents to pass. An interesting light is thrown upon the ætiology by those cases in which the septic factor is most in evidence. Similar changes of the whole gut are to some degree common with all forms of septic peritonitis, but in some, as in the "ileus duplex" described by Sampson Handley, one or two loops of gut are alone affected. In either, the condition, as in the case of the stomach, gradually fades away below.

The profound dilatation, the complete absence of peristalsis and of any organic obstruction, the relative frequency with septic conditions, and often the failure to obtain relief by drainage, make it evident that both ileus paralyticus and the more local condition of ileus duplex are due to a paralysis of the gut. In spite of the many theories put forward to account for acute dilatation of the stomach, this condition, as first suggested by Campbell Thompson, seems undoubtedly to be of the same nature, for in certain cases, as in those reported by Richardson and Lee, it arises with almost startling suddenness during the course of an operation. In nearly all cases there is no evidence of any obstruction, either mechanical or spasmodic, and its onset or progress is entirely uninfluenced by the performance of gastro-enterostomy.

The seat of the lesion appears to be in the nerv paths and not in the muscle coats, for adrenalin give by mouth seems to act directly upon the gastri muscle and to cause it to contract, while hypoderm injections of eserine salicylate have long been know to have a beneficial effect upon the intestinal musc in cases of ileus paralyticus. Koehler believes tha the condition is not one of complete paralysis, but rather a balance of the two nerve systems at a lowe level than normal, and he states that if the cœlia plexus be injected with nicotine, whereby the sympa thetic impulses are removed, there is the immediat onset of peristaltic movements. Similar effects hav been claimed to follow the administration of a spina anæsthetic. Mauclaire and others have produce evidence of the value of this method, but as it wa in many cases unfortunately given to patients sufferin with mechanical obstruction it has been discredited

Symptoms.—In either case the symptoms are du to a rapid distension of the viscus with gas and fluid and to an increasing collapse from toxic absorption When the stomach is mainly affected, vomiting—a first regarded as simple post-anæsthetic—become increasingly severe until it consists of an almos effortless emission of foul, brown fluid, which is a overflow rather than an actual vomit, for the patien continues to complain of discomfort and distensio in the epigastrium, and the stomach can be see enormously dilated even in the presence of almos constant vomiting. No peristaltic waves are seen When the condition is mainly in the small intestin the vomiting is at first less, and the abdomen evenl distends. Neither flatus nor fæces is passed, an later vomiting of a foul brown fluid, similar to tha seen with an acute mechanical obstruction, occurs In either case there is a rapid collapse.

Treatment.—Since the condition is paralytic i nature, any form of treatment will have to aim a restoring the power of contraction to the paralysed muscle. It is as important, as with any other exhausted portion of the neuro-muscular system, to provid adequate rest, and it is essential to realise tha absolute rest to the stomach and intestine wil generally prevent the onset of the condition. A few years ago the medical profession was obsessed with the idea that the one thing necessary after an operation was to obtain an action of the bowels, but with a wider appreciation of the fact that no aperient whatever should be given, either by mouth or hypodermically, for two or three days after an operation, and that morphia should be freely allowed, these conditions are becoming rarer. The value of such a line of treatment is clearly shown in cases of early acute obstruction from carcinoma of the colon. A patient is brought in with obstruction who is already vomiting and becoming distended. Colostomy is performed, but the gut is not opened. If morphia is then given it will frequently be found that all the acute symptoms entirely disappear, and the opening of the colostomy, instead of having to be performed within a few hours, can often be delayed for several days.

In the early stages it may still be possible to bring about a cure by directly stimulating the muscle which is only slightly exhausted. I am a great believer in the administration of suprarenal extract for slight dilatations of the stomach. I originally gave this where there was a post-operative gastric hæmorrhage, but in some mild degrees of dilatation it was difficult to determine whether the dark-coloured vomit was due to a small hæmorrhage or to the early onset of dilatation. Suprarenal extract was given in the belief that the primary change was a hæmorrhage, and it was found that the stomach contracted well and

vomiting ceased. It is my custom to give 1 drachm of the commercial extract of 1/1000 with 1 drachm of water every hour for six doses. In the case of the intestine, eserine sulph., administered hypodermically in doses of gr. 1/200, may have a similar effect upon the muscle. The muscle cannot be rested while it is stretched, and, therefore, if dilatation is actually present the viscus must be emptied. With the stomach, frequent washes are essential. If the patient is turned over on his face with the thorax well supported on pillows natural emptying may be aided. With the intestine, an enterostomy may be required, but this is not so satisfactory, for it is almost impossible to empty the whole length of the gut, and even if a large portion be threaded over a glass tube it will probably refill. If only one loop be affected the gut should be drained from above. In "ileus duplex" Sampson Handley accomplishes this by means of an ileo-cæcostomy combined with cæcostomy. Any other form of operative treatment, such as a lateral anastomosis, is almost certain to fail, since the wall of the gut is completely paralysed.

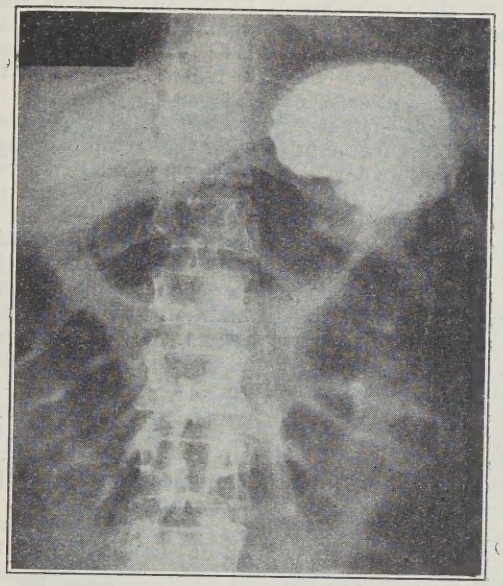
Relative Paralysis of All Vagal Impulses.

There is a very common but heterogeneous group of conditions in which abnormalities of the neuromuscular system are not yet proved to be present, although there is considerable suggestive evidence of such a change which would fully explain the clinical symptoms. These conditions are all characterised by delay in emptying, by dilatation, and by the absence of any visible obstruction or of hypertrophy of the wall behind the suggested obstruction. In many cases there are definite areas of spasm. In fact the changes are precisely those that would be expected to follow diminished action of the vagus or overaction of the sympathetic.

Ætiology and Pathology.—The majority of these patients show the general characters of visceroptosis, and are for the most part females. In them the alterations in the gut movements form only a part of a series of abnormalities which may be classified as: (*a*) changes in body structure; (*b*) alterations in mentality; and (*c*) visceral changes. The latter consist of the presence of dilatation and atony with ptosis, and the presence of accessory membranes and bands.

The stomach, as a rule, is lower than normal, though all ptotic stomachs may not give symptoms. It is usually atonic and is often dilated, and there is nearly always considerable delay in the emptying, as shown by X ray examination. Although the diminution in the rate of passage of the contents is very constant, areas of spasm are frequently found. As a general rule these are shown by a notch or depression in the greater curvature, which used frequently to be mistaken for an hour-glass stomach. They are, however, more limited, they disappear spontaneously or after the administration of eserine or amyl-nitrite, and no meniscus of a lesser curve greater is to be found. Occasionally the spasm may be much more extensive, so that the whole pyloric and even the tubular part of the cardiac portion of the stomach may be involved, giving rise to an X ray picture closely resembling that of a leather-bottle stomach (Fig. 2). In others the spasm is localised to the pylorus and appears to lead to considerable delay in emptying. This variety has been given the special designation of pylorospasm. It not infrequently occurs as a reflex phenomenon with lesions situated in other portions of the abdomen, such as the appendix or gall-bladder, or is found even more commonly with gastric or duodenal ulcers. It may, however, occur quite apart from such local lesions, and is then regarded by many as an important factor in producing symptoms, especially in those who are the subjects of general ptosis. Even in these cases, where the spasm is limited to the pylorus, the stomach is thin and flabby and does not show the muscular hypertrophy such as is found with organic obstruction. At operation the tendency to spasm is always very marked, so that any portion of the stomach which is picked up during the gastric examination will show areas of contraction which form a ridge about 1 in. long and $\frac{1}{4}$ in. wide, running either transversely or longitudinally across the stomach. Within a few minutes this area of spasm disappears, leaving the normal soft wall. In the past, such areas were frequently mistaken for the base of an ulcer, and a gastro-enterostomy was incorrectly performed. The nature of these changes has perhaps led to more controversy than any other lesion in surgery, but every theory has so far failed to explain in a satisfactory manner the cause of the pain and delayed emptying. Some dilatation and membrane formation is found in every case, and it therefore seems certain that these changes are in some way connected with the presence of pain. The bands and ptosis, and possibly the changes in body structure, are undoubtedly congenital faults, and, as Briggs has shown, are hereditary in nature, but the symptoms will not occur unless there be an added loss of tone. There is never any true organic obstruction, for it is a matter of common knowledge that muscular hypertrophy is invariably absent, and although in all cases there is a delay in the passage of the visceral contents there is never any evidence of a localised mechanical obstruction. Moreover, Hurst has conclusively proved that a dropped and atonic stomach or colon may be found in patients who are free from all symptoms, such a position being present merely as an anatomical variation. The part taken by these various factors in producing symptoms has been admirably and exhaustively reviewed by

FIG. 2.



Widespread gastric spasm resembling a "leather-bottle" stomach. No gastric lesion was found at operation.

Bedingfield, who sums up by saying that "the association of malnutrition, poor muscular tone, and an abnormal mental reactivity is characteristic of this group of cases," and that the association appears to depend upon a congenital, possibly inherited, inability of the individual to adapt herself satisfactorily to the various stresses and strains of life. Whatever be the cause, there can be no doubt that the dilatation of the viscera and the stasis of the contents is dependent upon a neuromuscular functional error.

The symptoms date from very early life; they are almost continuous without the definite periodicity of a chronic ulcer; the pain, although often severe, has no clear relationship to the ingestion of food; it may be localised to the stomach or referred to any portion of the intestinal tract; vomiting is frequent and does not give complete relief; there is no loss of appetite and constipation is very common.

Treatment.—When it was believed that the ptosis was the chief factor in causing the symptoms many operations were devised to fix the stomach in a normal position. They are being generally abandoned now that it is becoming more widely recognised that the low position of the stomach is usually only a variation, and that the symptoms are rarely cured by fixation. In all cases of this nature the treatment should primarily be medical. In addition to the changes in the stomach, the abnormalities in the body structure, and especially the mental changes, will require attention. Belladonna is generally advocated as a means of overcoming the spasm, but it is of interest to note that Ritvo and Weiss were able to demonstrate under X rays that it was immediately relieved by eserine given by mouth or hypodermically; which drug also increased peristalsis and heightened the tonus, thus supporting the view that the changes are due to a relative weakness of the vagal impulses. When the spasm is confined to the pyloric sphincter Deaver and other surgeons have advocated its free division. Acting on the belief that the vagal impulses are weakened, operations have been devised whereby the inhibitory sympathetic impulses have been removed by dividing the nerves in the lesser omentum or in the stomach wall itself. Gomain, in 1914, and Jianu, following Gomain's technique, successfully excised the semilunar ganglion and the splanchnic nerves for the gastric crises of tabes. Pribram, regarding these cases of spasm as of a somewhat similar nature, states that he was able to cure by excision of the cœliac ganglion a patient who had had eight previous operations for gastric pain.

DUODENAL ILEUS.

A mild degree of dilatation and apparent atony of the duodenum is common in all the visceroptotic cases, and even when the duodenal condition dominates the clinical picture Wilkie has shown that it is most commonly found in adult females who are the subject of ptosis. The condition was known to Rokitansky in 1842, and cases were reported by Fagge in 1872, but it has only been widely recognised since the later work of Wilkie. Here, as with the other varieties of neuromuscular change, the symptoms, as Barling has shown, often date back to childhood, suggesting a congenital origin. At first associated only with discomfort and flatulence, it later gives rise to severe epigastric pain which is most marked from one to two hours after food. With it there is loss of appetite and often headache, and there are frequent exacerbations of more severe vomiting. On examination the general characters of virginal ptosis are nearly always in evidence, and splashing can be elicited over the dilated stomach, but rarely, if ever, is there any visible peristalsis. The change appears to be a chronic variety of acute dilatation of the stomach and, like that condition, has been thought to be due to obstruction from traction of the mesenteric vessels. Wilkie has found that in some cases the duodenal wall is hypertrophied, and that there is coexistent ulceration of the duodenum in some 20 per cent. of the cases. In one of my own eight cases there was a line of superficial ulceration at the position of the mesenteric vessels, but in the majority there was no hypertrophy whatever of the muscular wall, and the dilatation faded away and showed no sharp termination or other evidence of mechanical obstruction; thus, although a few cases would appear to be mechanical in origin, I think there can be no doubt that the majority are atonic in character, and are due to a neuromuscular fault. In support of this, my own experience has been that only a few are relieved by duodenojejunostomy.

ENTEROSPASM.

Spasm of portions of the small intestine is probably one of the factors in causing pain in the visceroptotic patients, and in them there is often dilatation of the loop of gut proximal to an ileal kink. There are also well-recognised cases where symptoms of acute intestinal obstruction have necessitated an operation but when the abdomen is opened a dilated and apparently obstructed loop is found to terminate below in an area of tight spasm with no organic obstruction. The nature of the pain found in many cases of calcareous mesenteric glands is also suggestive of the presence of localised intestinal spasm. In none of these cases of neuro-muscular obstruction which are all relatively rare, is there any hypertrophy of the wall of the gut proximal to the spasm. The condition can usually be relieved by dietetic and medical measures.

COLONIC SPASM.

The pathological changes found in the colon in cases of visceroptosis and the symptoms they cause are in every way comparable with those of the stomach and small intestine, although in the colon accessory membranes and bands are generally more in evidence. The symptoms are most frequently allocated to the site of the atonic and dropped cæcum—the right-sided ptosis of Coffey. In such cases there is marked delay in the passage of the contents of the colon but never is there any evidence of mechanical obstruction or of hypertrophy of the dilated gut. Although in these cases areas of spasm may occur and may be seen during X ray examination, there are others usually seen somewhat later in life in which spasm of the descending and pelvic colons is the outstanding feature. It is more persistent than in the last group and tends to be more localised, while often giving rise to severe pain. Owing to the later age of the patient it is therefore very prone to be mistaken for carcinoma of the colon. Ryle has reported a series of 50 such cases. He lays stress upon the fact that although the average age was 39, 66 per cent. of the cases were females—but were usually thin, spare, nervous, anxious, and neurotic—thus showing the relation of this type to the variety with congenital visceroptosis. In my own series, however, examples also occurred in patients, generally females, who were more elderly, who showed none of the stigmata of virginal ptosis and presented only a short pain history, so that the diagnosis of carcinoma was even more closely resembled.

In this variety also the affected portion of the intestine shows no evidence of mechanical obstruction

and no hypertrophy of the gut behind the areas of spasm. In some cases there is an associated colitis to which the spasm is possibly secondary. Ryle found 11 of his 50 cases had such mucous colitis. In other cases it may occur with lesions elsewhere in the abdomen, and thus is possibly reflex. In one of my own cases there was a carcinoma of the stomach, but in others no cause can be found. The chief complaint is pain, which may sometimes only consist of a dull aching, but more frequently occurs as attacks of severe colic, very suggestive of an incomplete obstruction. This may have been sufficiently severe to have necessitated the administration of morphia. During these attacks the contracted portion of the intestine may be palpable as a tender lump which is easily mistaken for carcinoma. An X ray investigation after an opaque enema will reveal a filling defect, a segment of the colon being emptied and failing to fill throughout the whole examination. If the defect is sharply limited above and below, a spasm is suggested, but in others the outline appears to be more irregular and the similarity to carcinoma is thereby increased (Fig. 3). The condition will, as a rule, yield readily to medical treatment, but owing to the uncertainty in the diagnosis and the possibility of the presence of carcinoma, an operation may be required.

Probably at a later stage of the same condition may be seen cases in which the pelvic colon becomes considerably dilated and atonic, although attacks of spasm may still occur, and the patient suffers with an increasing degree of constipation. These changes may progress until the condition resembles clinically one of Hirschsprung's disease, and may require treatment upon somewhat similar lines.

Relative Paralysis of the Vagal Impulses to the Sphincters.

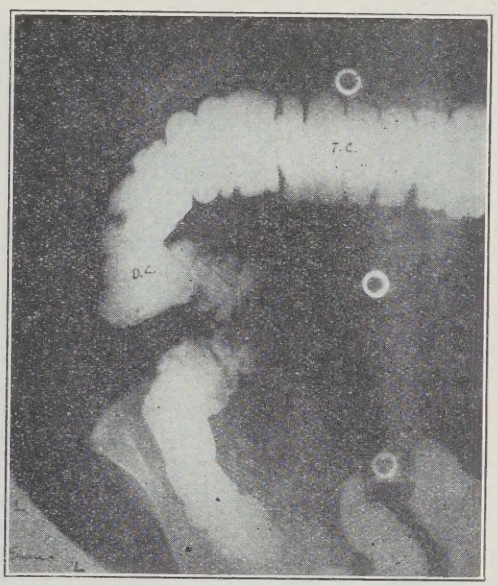
The third group is characterised by the fact that there is an enormous dilatation and hypertrophy of a portion of the canal, but a most careful post-mortem examination fails to reveal the presence of any obstruction. The change is sharply limited below, usually at the level of one of the fixed sphincters, and although in life X ray investigation shows that there is an obstruction at this site, yet after death no change can be demonstrated in the muscle of the sphincter.

CARDIOSPASM, OR ACHALASIA OF THE CARDIA.

Ætiology and Pathology.—The condition may occur in either sex. In my own series of 33 cases, 16 were males and 17 females. Most commonly the patients seek treatment at or about middle age, the average age of my cases being 48. I have, however, for long been convinced, owing to the enormous amount of dilatation and hypertrophy, that the change has gradually developed since birth. In later life, owing either to increase in weakness or to the sudden onset of some acute illness, compensation has failed, and symptoms have developed. This view is now supported by the fact that a considerable number of cases have been reported in young children and others in adults in whom symptoms have dated back for many years. Langmead has reported a case in a child of 16 months and Still two patients aged 2 and 5, in all of whom the symptoms dated back to birth. Poynton also has reported a case, aged 9, with a history from the age of 11 months, and Parkes Weber collected reports of 11 cases occurring in the first seven years of life. In the 33 cases in my own series, the youngest was aged 10 years, with symptoms from birth. In several others the symptoms dated from an acute illness suggesting that this was the cause of the failure of compensation in a long-established condition. It would therefore appear that the lesion is often a congenital fault.

The pathological changes consist of an enormous dilatation extending from just below the cricoid cartilage. In the earlier stages it ceases abruptly at the level of the diaphragm, but later extends to the cardiac orifice. It was the termination at the level of the diaphragm which formerly gave rise to the belief that the obstruction was caused by spasm of that muscle. With the dilatation there is usually some lengthening, and owing to the varying combination of these two changes different varieties are

FIG. 3.



Two areas of spasm of the descending colon, the upper of which closely resembles carcinoma. (The print has been reversed.)

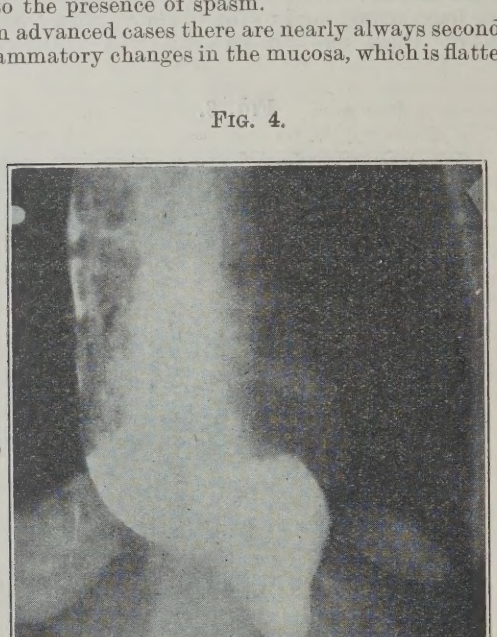
described. Moore, who has paid much attention to the pathological aspect of this subject, described a fusiform variety which is the commonest; a flask or pear-shaped type and an "S"-shaped form which is uncommon. In advanced cases the dilatation may be sufficient for the œsophagus to contain a pint or more. It is always the most characteristic feature as seen in the X rays (Fig. 4), and there is no other condition which causes so extreme a dilatation. In association with the increased capacity there is an enormous hypertrophy of the muscular wall, and it is this change which so sharply differentiates the conditions in this group from those in the last. The amount of hypertrophy is commensurate with the dilatation, but in some cases, presumably early examples in which there is good compensation, the hypertrophy dominates the picture. The thickening of the wall commences gradually above at the level of the cricoid cartilage and, increasing below, ceases abruptly with the dilatation either at the level of the diaphragm or the cardiac orifice. The cardiac sphincter shows no hypertrophy, a point on which Hurst lays great stress in his argument that the condition is a failure of the sphincter to relax rather than to go into spasm. I know, however, of no condition of proved spasm of involuntary muscle which is associated with hypertrophy. The

conditions always thought to be spasmodic never show any such change, but, as Hurst says, these also are probably conditions of achalasia. He described hypertrophy as occurring with spasm of the anal sphincter, but I have been unable to find in my own experience an example of such a change.

In my own cases a bougie passed down the œsophagoscope was always found to be gripped by the sphincter in so definite a manner that it could readily be demonstrated, and there was thus no doubt as to the presence of spasm.

In advanced cases there are nearly always secondary inflammatory changes in the mucosa, which is flattened

FIG. 4.



Radiogram of case of "cardiospasm."

and smooth and may show areas of superficial ulceration. In long-standing cases there are patches of leukoplakia which may pass on to carcinoma. Souttar has reported such a case, and Hurst mentions several such in the literature and in his own experience.

The enormous hypertrophy of the wall of the œsophagus, the powerful contractions which may be seen on radiographic examination, and the forcible ejection of the œsophageal contents make it evident that there is no paralysis of the œsophageal wall. For this reason, and because no obstruction could be demonstrated, Mikulicz suggested that there was a spasm of the cardiac sphincter; Hurst, however, strongly supports the view first enunciated by Einhorn that there is a failure of the sphincter to dilate rather than a spasm. He bases this view largely upon the fact that he could find no spasm, and that a bougie could be easily passed. He therefore calls the condition "achalasia of the cardia." He supports the findings of Kraus that there is a degenerative change in the vagus, and he and Rake were able to demonstrate such a lesion in 11 cases which were examined. If this degeneration extends upwards beyond the cardiac area it is remarkable that even in the late stages the muscle of the œsophageal wall is greatly hypertrophied and forcible peristaltic waves are present. Hurst also states that inflammation of the œsophagus may give rise to a secondary spasm of the sphincter. This may be the explanation of why a bougie was never gripped in his cases, while in my own—which were probably more advanced examples—it was always firmly gripped by the sphincters.

Symptoms.—In most of my cases the symptoms have been present for many years. In my youngest patient, aged 10, they dated back to birth. In some cases there has only been a short history which has then not infrequently dated from an acute illness suggesting that this has been the cause of the failure in compensation. The onset may be with pain or a feeling of obstruction. If care be taken in obtaining the details of the history of the early stages there is, as a rule, but little difficulty in making a correct diagnosis. The history is much more prolonged than with carcinoma of the œsophagus. The obstruction is variable, and in the earlier periods is often more marked to the passage of fluids than to that of solids. Sometimes the solid food sticks and only passes after the taking of a considerable amount of fluid, this probably forming a sufficiently high column to overcome the obstruction. In the earlier stages regurgitation occurs after the ingestion of a few mouthfuls, but later the œsophagus becomes so dilated that it may accommodate the whole meal before regurgitation occurs, and thus the condition may easily be mistaken for one of pyloric obstruction. In one of my cases a gastro-enterostomy had been performed elsewhere on this supposition. If the history has been carefully taken this mistake will be easily avoided. The nature of the obstruction should not be confused with an œsophageal pouch for in the latter the difficulty in swallowing increases as the meal progresses, and there is only the regurgitation of a small quantity of material, which is often foul. Diagnosis can always be confirmed by X ray and by œsophagoscopy. By the former, the site of the obstruction, the narrow but regular passage and the enormous dilatation of the œsophagus are characteristic; with the latter the large quantities of fluid moving up and down with respiration; the great dilatation and the smooth but contracted orifice below give a picture obtained with no other lesion.

Treatment.—The evidence that the condition is due to a relative paralysis of those vagal impulses which supply the sphincter is so strong that the rational procedure would seem to be to overcome the relative overaction of the sympathetic impulses by division of these fibres. Such an operation, however, is one of considerable difficulty, and would appear to be unnecessary in that powerful contractions of the muscle wall of the œsophagus are always present. I have been unable to find an account of the operation having been performed. The spasm of the sphincter or its failure to relax may be more readily overcome by forcible stretching. This has been performed by two methods. In the one, a dilator is passed from above. Whether this dilator be a simple or mercurial bougie, as used by Hurst, or a hydrostatic dilator as used by Plummer, it has the objection that the dilatation is relatively incomplete, and thus the condition tends to recur, so that the dilatation has to be repeated on many occasions. It is claimed by Hurst and Plummer that the measure of relief may be so complete that in the earlier stages at any rate the patient may be enabled to live a useful and comfortable life by its use. In my own series of 14 cases there have been 14 where this method has failed after prolonged trial. This is very possibly due to the fact that most of the cases which seek surgical aid are far advanced. Five cases in my

series were seen in the early stages and have been treated with dilatation with bougies with complete success. It is true that the dilatation has to be repeated at relatively frequent intervals, generally once a month, but they have lived and taken food in comparative comfort, one for nine years, one for six, two for four, and one for one year. The other method, which was first introduced by Mikulicz, is that of dilatation from below with the fingers, introduced through the opened stomach. The drawback of this method is that it is an operation of considerable magnitude. It aims at so forcibly dilating the sphincter, that the muscle-fibres, if not torn, are so widely stretched that they are permanently paralysed. There is thus the risk that on the one hand the procedure is not carried sufficiently far, so that after a time the paralysed fibres recover and the symptoms return. On the other hand, if the stretching is carried too far the mucosa may be lacerated, and severe hæmorrhage with later a fibrous stricture occur, or even the whole wall be torn and a fatal infection spread to the mediastinum. For this reason the dilatation must always be performed with the fingers, for with any form of instrument insufficient control would be obtained. In practice the results, if the method be carefully used, are so satisfactory that any of the more dangerous operations of performing an anastomosis between the stomach and the dilated œsophagus are unnecessary. Nor is it indeed likely that any operation upon the sympathetic fibres will give more satisfactory results.

My own series includes 33 cases in all. Of these, 22 were treated by digital dilatation from below through the opened stomach, 14 of them after the prolonged passage of bougies had failed. Of these 22, three died after operation, one, a patient with myocardial degeneration, from cardiac failure, one from post-operative pneumonia, and one from sepsis following a tear of the œsophageal wall from excessive dilatation. Of the remaining 19, 13 have remained in perfect health for periods extending up from one to 11 years. They can eat anything and have required no after-treatment. Six have not been complete successes; one of these was dilated with only one finger. The condition recurred and was dilated again to four fingers, since when he has remained in perfect health for four years. One developed a fibrous stricture, evidently from a tear of the mucous membrane, and has only obtained incomplete relief from the passage of bougies. Four have slight difficulty after seven, six, three, and one year respectively, but this is insufficient to require any further treatment, there being only an occasional feeling of obstruction which is relieved by a copious drink. When it is remembered that without treatment this lesion is steadily progressive, and not only causes grave discomfort but ultimately leads to profound wasting and starvation, going on to death, there is no doubt that this operation must be regarded as satisfactory, and with more experience may be looked upon to bring about a complete cure in the majority of cases.

PYLOROSPASM.

Conditions of spasm of the pyloric sphincter as a reflex phenomenon and as part of the relative paralysis of all vagal impulses have already been discussed. The well-known condition of congenital pyloric stenosis, and the rarer examples with a similar pathology which are found in adults, have by many been regarded as due to prolonged spasm of the pyloric sphincters, and the lesion is indeed often described as an example of the amount of hypertrophy which will follow a simple spasm. That the condition in young infants is one of spasm is, in my opinion, definitely disproved by the fact that it may occasionally be found in the fœtus, that so great a degree of hypertrophy would be impossible in the two or three weeks in which symptoms have been present, that it is frequently present in several members of the same family or in both of twins, that the hypertrophy persists in spite of complete rest by gastro-enterostomy, and I believe, in spite of the recent work of Wolff, that cases said to be cured by medical treatment are in fact only relieved in part, and tend to recur later in life. For these reasons I would insist that this change is a congenital deformity and is not in any sense of the word a neuro-muscular lesion.

It would be expected that with such definite neuro-muscular lesions as cardiospasm and Hirschsprung's disease, a precisely similar change would be found in the stomach; that is to say, one in which there is an enormous dilatation and hypertrophy of the stomach but no visible obstruction after death. It has, in fact, been claimed that such a condition does occur in young infants and that the visible peristalsis from the hypertrophied stomach may give rise to an erroneous diagnosis of congenital pyloric stenosis, but at operation the characteristic hypertrophy of the sphincter is not found. My colleague, Dr. K. H. Tallerman, tells me that he has seen one such case, but although I have for long been searching for such a condition I have failed as yet to find an example. It would, therefore, seem as though a relative paralysis of vagal impulses to the sphincter of the stomach, if it does exist at all, is of extreme rarity.

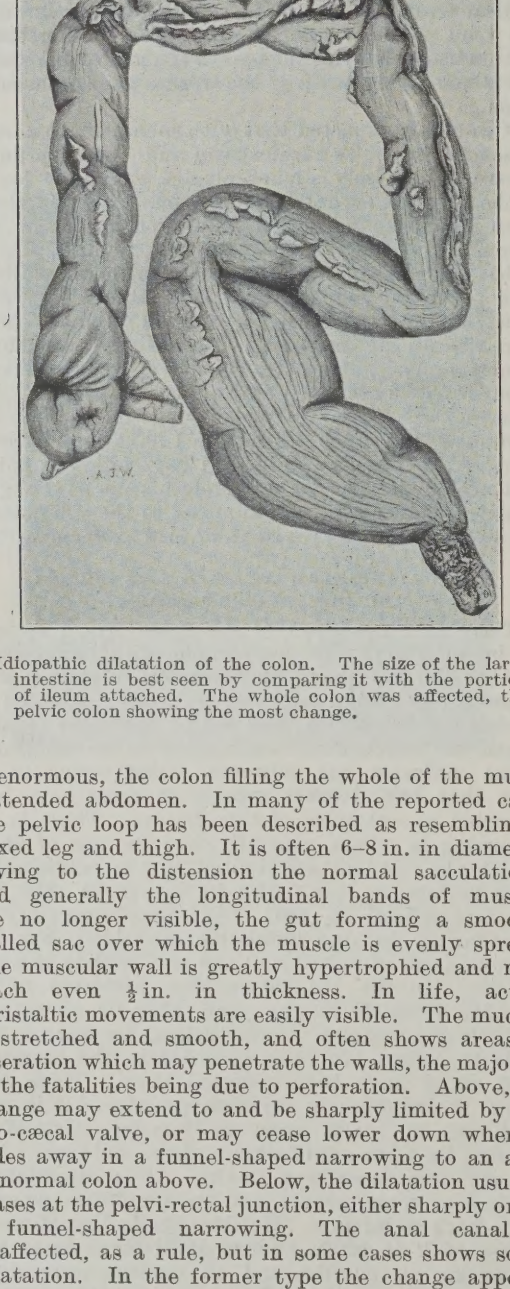
IDIOPATHIC DILATATION OF THE COLON: HIRSCHSPRUNG'S DISEASE.

There is a condition of the colon which appears to be in every way comparable with cardiospasm in that the gut shows an enormous dilatation with hypertrophy of the muscular wall and evidenced by profound constipation, and yet at operation or after death no mechanical obstruction is to be found. Some confusion has, however, arisen owing to the fact that two distinct groups of cases have been reported as examples of this disease. There is one occurring in adults, generally over the age of 50, in which the changes are limited to the pelvic colon. This variety, as was shown by Treves, in 1899, and by Lowenstein, in 1907, has almost certainly no relationship to true idiopathic dilatation, but is a chronic form of volvulus. The true variety is a rare disease. In the 131,000 patients admitted to the London Hospital in the years 1900–09, there were only four examples. Nevertheless, Lowenstein was able to collect 120 cases recorded in the literature, and many have been reported since. There have been 12 examples in my own practice. It is more common in males than in females, Hale-White stating that five out of six are of the male sex. Nine of my own cases were males. It is essentially a disease of young people, and the symptoms generally date back to infancy. Hawkins states that it always dates back to birth, and reported three cases aged 3 weeks, 10 months, and 12 months respectively. Ladd has also reported five cases in children aged 2 months, 3, 6, 7, and 9 years respectively, while Popper has had the interesting experience of observing the condition in each of twins aged 4 days. There can thus be no doubt that the disease is of congenital origin, although, as with cardiospasm, the onset of symptoms may be delayed for a long period.

The characteristic pathological change consists of an enormous dilatation and hypertrophy of the

gut (Figs. 5 and 6). As a general rule the whole of the colon from the pelvi-rectal junction to the cæcum is affected, although the change is generally more marked in the lower part of the gut. The dilatation

FIG. 5.



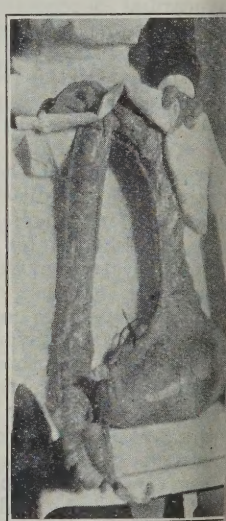
Idiopathic dilatation of the colon. The size of the large intestine is best seen by comparing it with the portion of ileum attached. The whole colon was affected, the pelvic colon showing the most change.

is enormous, the colon filling the whole of the much-distended abdomen. In many of the reported cases the pelvic loop has been described as resembling a flexed leg and thigh. It is often 6–8 in. in diameter. Owing to the distension the normal sacculations, and generally the longitudinal bands of muscle, are no longer visible, the gut forming a smooth-walled sac over which the muscle is evenly spread. The muscular wall is greatly hypertrophied and may reach even ½ in. in thickness. In life, active peristaltic movements are easily visible. The mucosa is stretched and smooth, and often shows areas of ulceration which may penetrate the walls, the majority of the fatalities being due to perforation. Above, the change may extend to and be sharply limited by the ileo-cæcal valve, or may cease lower down when it fades away in a funnel-shaped narrowing to an area of normal colon above. Below, the dilatation usually ceases at the pelvi-rectal junction, either sharply or by a funnel-shaped narrowing. The anal canal is unaffected, as a rule, but in some cases shows some dilatation. In the former type the change appears to end at the sphincter between the pelvic colon and rectum, in the latter at the anal sphincter. It is probable, however, that the sphincter action of this portion of the gut is not divided into separate portions, but that the whole of the anal canal should be empty and contracted by sphincter action, and that, as in the case of cardiospasm, the condition in the early stages terminates at the upper end of the sphincter, while in the later stages the upper portion may have dilated. Martin and Burden found that in 31 cas there was an abrupt change in the appearance of t mucous membrane between the sigmoid and t rectum.

Many theories have been put forward to explain t remarkable changes that are found. Barringto Ward even quotes 13. Many of these attempt show that there is a mechanical obstruction from t presence of a valve, kink, or volvulus, but there is doubt that no such obstruction exists. No narrowi can be found post mortem, and in life simple a opaque enemata may be easily passed. The mark hypertrophy of the gut wall and the visible and acti peristalsis make it evident that there is no paralys There is, therefore, a growing tendency to acce the view that the lesion is a neuromuscular fau Treves stated that he believed some of the cases be due to an error of innervation, a view that w elaborated by Hale-White and Shattock. The fa that the dilatation is sharply limited at the si of the sphincter below, and that after death t obstruction has disappeared, shows that the chan is identical with that of cardiospasm and due to error in the sphincter. As with the latter diseas Hurst believes that there is an achalasia rather th a spasm; the ease with which enemata may administered would certainly support this view, t condition being due to a relative paralysis of t vagal impulses to the sphincter.

Symptoms.—In most cases the symptoms date fro birth, but in others the obstruction is, as in the ca of cardiospasm, apparently overcome by the hype trophied muscle, and symptoms only appear compensation fails. There is a steadily increasing constipation, at first easily relieved with aperients and enemata, but later only with difficulty. In some curious cases there are prolonged periods of relief during which the bowels are opened regularly. The attacks of constipation, however, steadily increase in frequency and severity until the bowels are only opened once every week or perhaps even only once in every two or three weeks. At this stage there is considerable abdominal pain of a colicky nature. As the disease progresses, the abdomen becomes distended until it is enormous and may cause some embarrassment of respiration (see Fig. 7).

FIG. 6.

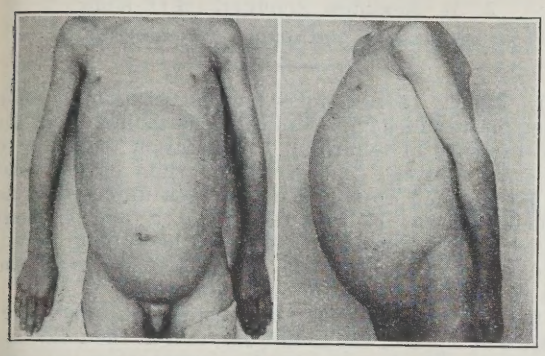


Idiopathic dilatation of colon. Specimen from boy aged 11.

In some cases the distension is uniform, but in others a localised area may be distinguished, due to the dilated pelvic colon. In this, hard scybalo masses may often be felt through the abdomin wall, and peristalsis of the gut wall is near always visible. Although the distension is so gre the patients may for some years appear to be remarkably good health, but later the evidences pressure are increased, the lower ribs being expande the diaphragm and heart pushed upwards, and t veins compressed so that the legs are œdematou there are visible and distended veins on the abdomin

wall and albuminuria is present. Occasionally, as in a case reported by Langmead, tetany may be present. In the later stages, attacks of subacute obstruction with increasing pain, absolute constipation, and vomiting occur. Thus, cases recognised in early life did not, as a rule, live to adult age. Of 24 cases studied by Crozer Griffith, in 1899, only three survived

FIG. 7.



Abdominal distension with Hirschsprung's disease in a boy aged 11.

childhood. Examination with the sigmoidoscope shows only an enormous dilatation of the pelvic colon, and there is no trace of any mechanical obstruction or valve. It is sometimes stated that a tight spasm of the anal canal can be distinguished, but in the 12 cases in my own series no abnormality could be made out. On X ray examination the enormous dilatation of the colon is often easily distinguished before any barium enema is given owing to the large amount of gas in the distended colon. A barium enema often does not greatly improve the picture, for the cavity is so large and contains so much fæcal material that the barium is badly distributed.

Treatment.—Until a few years ago it was believed that the fault lay chiefly in the wall of the gut, so that, although it was hypertrophied, it was failing to function in a correct manner. Hence, operative treatment was directed towards diversion of the contents from the affected portion of the gut. Discussion therefore centred around the relative merits of colostomy, ileocolostomy, and partial or complete colectomy. The two latter operations gave the most satisfactory results, and in some cases, as in two of my own series, appeared to bring about a complete cure. Ito and Soyesima found that of 21 cases of complete colectomy, 14 were cured, and Giacinto reports 80 cases of colectomy with 59 recoveries. It is probable that in these cases relief was gained owing to the fact that the contents of the pelvic colon after operation were fluid, and thus were more readily passed. The operation was, however, associated with a high mortality in patients often young and in poor health. According to more modern views, these operations were based upon a wrong conception of the pathology. If the cause of the obstruction is, as is believed, a spasm or an achalasia of the anal or the pelvi-rectal sphincter, the correct treatment would be to overcome this, either by forcibly and, if possible, permanently dilating it, or by removing the relatively overacting sympathetic impulses, and thus allowing the sphincter to dilate. Fullerton, being struck with the similarity of this lesion to cardiospasm, treated a boy, aged 2 years and 4 months, with forcible dilatation of the sphincters, at first with the fingers and later with a rubber bag filled with water. Five months later the child was free of all symptoms. This method is so simple, and brings the treatment into line with that of cardiospasm for which dilatation has been so successful, that it is worthy of further trial. Owing, however, to the well-known work of Royle, who, in his operations upon the lumbar sympathetic cord, found that a patient who had suffered with severe constipation was entirely relieved, attention has been more fully directed upon this line of treatment. In 1926, Bartle, and in 1927, Wade and Royle, advocated lumbar ramisection as a means of treatment. At the recent meeting in Winnipeg, Royle, Learmouth, and Wade all enthusiastically supported the method; Royle stating that it gave excellent results in all cases, and Wade reporting 14 cases with striking improvement in all but one.

Comment.

The conditions which I have described are not only of interest in that for many years they have led to much discussion as to their cause, but they direct attention to one of the most important problems of modern medicine. They all show a congenital and often an hereditary fault. In some the actual disease dates from birth, in others it is only the tendency which appears to be congenital. They also appear to be getting more frequent, so that together they now form a large proportion of all abdominal cases. With the control and consequent diminution of acquired disease there is no decrease, indeed there appears to be an increase in the congenital faults of the race. We hear to-day everywhere discussed the question of birth control, but what we, as a medical profession, must consider and discuss is whether there is not rather a need for compulsory birth control. It has always been a matter of astonishment to me that a race of people who will pay enormous sums for pedigree stock animals confine their attention, at great cost, entirely to environment when considering the benefit of the human species. Will the day come when it will be regarded as a criminal act for a couple to bear children before they are proved to be of good stock, and have shown that they are able to make some provision, either by insurance or investment, for the welfare of their children?

DONATIONS AND BEQUESTS.—Among other bequests, the late Mr. William Law, of Clevedon-drive, Kelvinside, Glasgow, left £3000 each to the Glasgow Royal Infirmary, the Glasgow Western Infirmary, and the Victoria Infirmary, Glasgow; £1000 each to the Sick Children's Hospital, Glasgow, and the Broomhill Home for Incurables, Glasgow; £500 each to the Seamen's Hospital Society ("Dreadnought"), Greenwich, the Home for Infirm Children, East Park, Glasgow, the Largs Convalescent Home, the Kilmun Convalescent Home, and £250 to Glasgow and West of Scotland Seaside Convalescent Homes, Dunoon.—Mr. Herbert Samuel Thrower, of West Heath-avenue, Golders Green, left by will, in addition to other legacies, £2000 to the Hampstead General Hospital, for beds for the benefit of employees of his firm, and, conditionally, £500 for general purposes, and £1000 to the Metropolitan Convalescent Institution towards the upkeep of the Bexhill Convalescent Home. The ultimate residue of the property will be divided between the Metropolitan Convalescent Institution, the National Institution for the Blind, King Edward Sanatorium at Midhurst, the Children's Hospital, Great Ormond-street, and the Mount Vernon Hospital.

THE TOXICOLOGY OF THALLIUM.

BY G. ROCHE LYNCH, O.B.E., M.B. LOND., D.P.H., F.I.C.,

SENIOR OFFICIAL ANALYST TO THE HOME OFFICE; DIRECTOR OF THE DEPARTMENT OF CHEMICAL PATHOLOGY, ST. MARY'S HOSPITAL; LECTURER ON FORENSIC MEDICINE AND TOXICOLOGY, WESTMINSTER HOSPITAL MEDICAL SCHOOL;

AND

J. M. SPENCER SCOVELL, M.D. EDIN.,

PHYSICIAN TO THE LONDON SKIN HOSPITAL.

IN March, 1861, Crookes,[1] whilst examining some selenium residues in a sulphuric acid manufactory for the presence of tellurium, had occasion to resort to spectral analysis. Observing a bright green band (λ 5350) which up till then had been unrecorded, he concluded that he had discovered a new element which he presumed to belong to the sulphur group and to which he gave the name thallium, from the Latin "thallus," a green or budding twig.

Lamy[2] independently discovered the same substance in April of the same year, and in the following year was able to isolate it in a state of purity and determine its properties. He suspected from the first that its compounds were toxic, for whilst engaged on this research he suffered from general lassitude and weakness of the lower limbs. He administered thallous sulphate to a number of animals, but did not record the dose given. They all died, some more rapidly than the others; the symptoms which he emphasised were weakness, abdominal pain, loss of appetite, trembling, paralysis of the hind limbs, and difficulty in breathing. Crookes, however, did not believe that thallium was toxic, and reported that he had taken doses of one to two grains and had felt no ill-effects.

Since then many observers have experimented with thallium, and in 1899 Richet[3] published an article on its toxicity in which he stated that chronic poisoning was commonly associated with generalised muscular atrophy. This observer, according to Cushny,[4] was the first to record the epilating effect of thallium, although Sabouraud is usually credited with the discovery. About this time (1898) it first appears to have been used therapeutically, when Combemale[5] advocated the use of the acetate for the night-sweats of phthisis and recommended doses of 10–20 cg. He found no toxic symptoms, but noticed that its use was followed by a complete and rapid loss of hair. Jeanselme[5] in the same year reported loss of hair in a phthisical patient who received 0·27 g. in three days, and Guinard[5] reported a similar event after nine pills each containing 0·05 cg. Buschke,[5] in 1900, and Betman,[5] in 1901, succeeded in producing a similar effect in animals. Pozzi and Courtade[5] used thallium iodide in doses of 0·01 g. daily for syphilis and reported good results, but it is doubtful whether thallium has any specific effect in this direction.

About 30 years ago Sabouraud first started to use thallium as a depilatory in ringworm, but eventually came to the conclusion that it was too highly toxic and dangerous and abandoned it. In all probability the reason of his failure to get good results was the administration of too large doses, for he apparently did not base the dose on body-weight. Attempts have also been made to use thallium salts in the form of a cream, as a local depilatory, but Dixon states most definitely that unless thallium is absorbed it has no epilating action, and when applied locally

it has no effect whatever. After Sabouraud abandoned the treatment, it does not appear to have been used to any extent until Cicero,* of Mexico, in 1909 attempted to use thallium for ringworm. In 1918 he published a favourable report of 439 cases, and followed this up in 1922 with a further report. In Europe, however, the treatment has only been revived recently, and Buschke has elaborated a standard system of dosage for general use.

In 1914 Buschke [6] reported his first experiments on rats; he came to the conclusion that the alopecia produced by thallium salts was due to nervous influences, and later, in 1922, he suggested that the epilation was produced in some way through the ductless glands. In 1926 Buschke, Langer, and Peiser [6] treated a number of children suffering from ringworm and fixed the minimum dose for producing epilation at 8 mg. of thallium acetate per kg. of body-weight. The drug was given by mouth in a single dose, sweetened, and on an empty stomach, as they found that if it were taken with food epilation was not so complete. Buschke also emphasised the importance of vigorous local treatment during epilation.

This method of treatment is now widely used, and many observers have published their results. Dowling,[7] who was one of the first to use the method in this country, is of opinion that 8 mg. per kg. is not always sufficient to bring about epilation, and he recommends 8–9 mg. per kg., using 8·5 mg. generally and 9 mg. for dark-haired children who do not epilate so easily and in those cases where the tinea is most marked on the crown of the head, as the hair does not come out so readily in this region. In all cases the children are weighed nude, and a full clinical examination, including that of the urine, is made. If these precautions are carried out, it is stated that no toxic symptoms should appear. They occur, if at all, about eight or nine days after the dose; they take the form of joint pains in the lower limbs, loss of appetite, drowsiness, and hypochlorhydria. The administration of hydrochloric acid will generally correct the last condition, and as some degeneration of the thyroid and suprarenals has been noted in several cases, administration of these glands is suggested.

It is now universally agreed that it is unsafe to administer an epilating dose to adults or to children about 10 years of age. Recently the tendency has been to give the drug only to younger children. The younger the child the greater the tolerance, and a smaller dose per body-weight is, of course, required. If these points are observed the advocates of this treatment maintain that it is perfectly safe, and that any untoward symptoms are only due to a personal idiosyncrasy, an accidental overdose, or impurities in the drug, although there should not be the slightest difficulty at the present time in obtaining thallium acetate in a state of chemical purity, nor should it deteriorate in solution. With the increasing use of this drug attention has been directed to the mechanism of its characteristic action.

Dixon [8] is of opinion that it acts through the autonomic nervous system, and support to this theory is given by the findings of other workers—namely, that the hair of the scalp only is under the trophic influence of the internal secreting glands through the sympathetic nervous system, and therefore the hair of the rest of the body, including the internal two-thirds of the eyebrows and a fringe at the edge of the forehead, does not come out. Cortella [9] has experimented with white rats, giving them daily a very small quantity of the drug (1–2 c.cm. of a 1–50,000 solution of thallium acetate in milk) with the object of ascertaining if any changes occur in the central nervous system with this dosage. He is of opinion that there were changes and that they were proportional to the dose given, and although with minute doses body-weight increased, wasting always occurred with toxic doses.

* As we have not been able to obtain a copy of these reports, we are not in a position to state the number of toxic cases, if any, which occurred in Cicero's series.

Chemistry of Thallium.

In the periodic classification of the elements the position of the metal falls into group 3 which, except for boron and aluminium, contains some of the rarest elements. Group 3 is subdivided into two subgroups A and B, and it is to the latter group that thallium belongs. Although it has certain properties similar to those of boron and aluminium, thallium presents certain differences which rendered its correct place in the periodic classification a matter of speculation for some years. Thus the more stable salts are monovalent—i.e., Tl′ as opposed to the less stable trivalent salts (Tl′′′). Boron and aluminium only function as trivalent elements (B′′′ and Al′′′). Thallium, further, shows many chemical properties in common with lead, which is next to thallium in order of atomic weights (Hg : 200; Tl : 203; Pb : 207), especially in respect to the halogen derivatives; thallium, moreover, is a soft malleable metal like lead. The thallic (Tl′′′) compounds—e.g., Tl_2O_3, on the other hand, resemble those of boron and aluminium—e.g., B_2O_3 and Al_2O_3. There is also a resemblance to metals of other groups—e.g., silver, potassium, and mercury. It is noteworthy that thallium, from a toxicological point of view, shows a distinct affinity for nervous tissue, as will be seen in the cases under review, and the profound effect that this metal has on the central nervous system is especially noticeable in the three cases of poisoning which we have examined. In this respect there are many points of similarity to lead.

Thallium is used in the manufacture of optical glass when a high refractive index is required. It is also used in the production of tungsten lamps, and has photo-chemical and photo-electrical properties.

Three Cases of Poisoning by Thallium.

The three cases—A., aged 10 years; B., aged 7 years, and C., aged 5 years—were brothers, and attended a skin hospital in London on Feb. 28th, 1929. They were found to be suffering from small-spored ringworm of the scalp; this was confirmed microscopically. They were well-developed healthy boys and the usual medical examination was made. A. weighed 4 st. 4 lb., B. weighed 3 st. 13 lb., and C. weighed 3 st.

The drug was administered on March 14th, when each received a dose of a solution of thallium acetate which, by an error of the dispenser, was made up ten times too strong. It was intended to give the two eldest boys 0·25 g. or 3·9 gr. and 0·23 g. or 3·6 gr.—i.e., 8·5 mg. per kg. of body-weight. The youngest was to have received 0·18 g. or 2·8 gr.—i.e., 8·9 mg. per kg. of body-weight. Actually each received ten times this quantity—namely, 39, 36, and 28 gr. respectively.

The boys returned home and went to bed as usual at 8.30 P.M. feeling perfectly well. About one hour later B. complained of pains in the stomach and sore-throat, had a hard, sharp cough, and was very restless. A little later A. complained similarly, and both were unable to swallow when water was given them. They became drowsy and passed a fairly peaceful night, during which B. vomited a little. In the morning A.'s face was drawn and he complained that he could not open his mouth or eyes, and by this time the youngest was complaining in a similar manner. They all remained drowsy during the day, and about 7 P.M.

that evening B. seemed much worse. When the doctor arrived B. was dead and A. was tossing about with jerky convulsive movements; his eyes were closed but the pupils were widely dilated. Frothy mucus was escaping from the nostrils and mouth, and the breathing was of the Cheyne-Stokes type. The pulse-rate was rapid and the extremities cold. He lived only a few minutes.

The next morning the youngest child was admitted into Westminster Hospital under Dr. D. H. de Souza, to whom we are indebted for the following notes. The child was then in a semi-conscious condition; there was no vomiting or diarrhœa, but the throat was sore, with inability to swallow. The temperature was 97·6° F., the pulse-rate 120, and the respiration-rate 25. The eyes reacted to light, and there were rhonchi all over the chest. The child seemed to improve slightly during the first part of the night, but died suddenly about 4 A.M.

POST-MORTEM EXAMINATION.

We are indebted to Dr. W. D. Newcomb for the following notes.

The children A., B., and C. received such a large dose that death ensued relatively early, and one would expect the changes in the organs to be different in cases dying after a longer time. The lesions in these cases were severe parenchymatous degeneration in all the organs examined. There were slight variations in the three cases, but these are explicable by the differences in age. All had approximately the same dose per kg. of body-weight and, as might be expected, the two eldest died first with more acute changes in the various viscera. In the youngest, who lived three days, there was time for the degenerations to become more obvious.

The *stomach* in each case contained a little mucus and showed submucous petechial hæmorrhage. In all the *hearts* there was a remarkable degree of fatty degeneration with "tabby cat" distribution. This was most marked in the youngest child, who survived longest. In the child who died first the lesion was confined to the left side, but in the others it was present in both ventricles. A slight perivascular fatty infiltration and scattered leucocytes could also be seen in each case. The *livers* showed congestion and fatty degeneration situated in the centres of the lobules. The condition was most marked in the youngest child, and here there was also some peripheral fatty infiltration. The *kidneys* were congested and showed toxic changes which varied considerably in the three cases. In the middle child, who died first, the capillary engorgement was intense, the glomeruli were swollen, and a little fat was present in the ascending limb of Henle. Severe cloudy swelling and necrosis of cells was also seen in the convoluted tubules. In the youngest child the congestion was less marked, but more fat was present in the Henle tubules, and karyolysis of the nuclei in the convoluted tubules was prominent. The eldest child showed an intermediate condition The *spleen* was congested and showed an excess of eosinophilic leucocytes in the pulp. This was most marked in the eldest, and probably indicated an eosinophilia in the blood. This has been noted in other recorded cases of thallium poisoning, but it is doubtful whether it is really due to the drug. It is very unlikely that such a change could occur as quickly as 29 hours after poisoning and, as many cases of ringworm show eosinophilia, this would appear to be the most likely explanation. The right suprarenal of the eldest child was available for examination, but no changes were found in it other than those accounted for by post-mortem decomposition.

It appears, then, that in large toxic doses thallium acts as a mild irritant to the stomach. It poisons the more highly specialised cells of the body, causing marked fatty degeneration in heart and liver and necrosis in the kidney. These changes are rather like those seen with the phosphorous group of poisons, but differ in that the fatty degeneration is most marked in the myocardium. In this respect thallium appears to be unique.

ANALYSIS OF THALLIUM IN VISCERA.

The estimation of thallium in viscera or urine presents no great difficulty. A weighed quantity of the material is broken up with hydrochloric acid and potassium chlorate by the method of Fresenius and von Babo and, when solution of all the material except the fat has been achieved, the liquid is filtered (well washing the precipitate), and the filtrate boiled until practically all the excess of chlorine has been driven off or removed by the sulphur dioxide method. If necessary it is filtered again, discarding the precipitate. To the filtrate ammonium chloride and ammonia are added until it is distinctly alkaline, and it is then again boiled. The precipitate, which consists of iron, calcium, and magnesium, chiefly in the form of phosphates, is filtered off and discarded. It may be advisable to add a small amount of calcium chloride solution to the liquid before the ammonia to ensure complete removal of phosphate.

The filtrate is then saturated with sulphuretted hydrogen or an excess of freshly prepared ammonium sulphide is added; a black precipitate is then formed. This precipitate is filtered off, well washed with dilute ammonium sulphide, and finally with distilled water. It consists of thallium sulphide (Tl_2S), together with traces of other metals which precipitate with sulphuretted hydrogen in alkaline solution and which have not been previously removed, but so far as toxicological analyses are concerned the only likely metal to be present—and then only in traces—is copper. When the precipitate is completely washed it is dissolved off the paper with hot dilute hydrochloric acid. The thallium is converted into thallous chloride (Tl Cl) and any trace of copper which was present as the sulphide remains behind, for this sulphide is insoluble in dilute hydrochloric acid. To the solution ammonia is added in slight excess and the liquid is boiled. If the process of separation has been complete no precipitate should occur at this stage. Any precipitate should be filtered off and discarded. The filtrate is then made very faintly acid with hydrochloric acid, and excess of potassium iodide solution is added. An immediate yellow precipitate of thallous iodide (Tl I) forms. As there is some tendency for thallous iodide to come down in colloidal form, the liquid should be boiled and allowed to stand for 12 hours.

The precipitate is then collected in a weighed Gooch crucible and is well washed, first with potassium iodide solution and subsequently with alcohol, until the washings give no reaction for an iodide. The crucible is then dried at 120° C. until constant weight is obtained. Although thallous iodide is very slightly soluble in water (1–17,000), it is almost completely insoluble in potassium iodide solution and in alcohol, so that filtration in the cold and washing with these reagents will give an accurate estimate of the amount present. The iodide after weighing may be confirmed as thallium by dissolving it in a solution of sodium thiosulphate, in which it is only dissolved with difficulty, whereas lead iodide is readily soluble. Finally, some of the iodide may be heated in a Bunsen flame on a platinum wire and the characteristic green line in the spectrum obtained.

AMOUNTS FOUND IN THE VISCERA EXPRESSED AS THALLIUM ACETATE.

—	Case A.		Case B.		Case C.	
	grains.	mg.	grains.	mg.	grains.	mg.

B, who died first, had eliminated less of the drug than A, who was given a larger quantity.

Dangers of Thallium.

Although the three fatal cases which have prompted the publication of this article were purely accidental and can in no way be used as an argument against the use of thallium in the treatment of ringworm (for regrettable incidents of this type have occurred with many drugs), a survey of the literature of the toxicology of thallium has made a deep impression on us, and we think that some useful purpose is served if a warning is given of the dangers of the drug.

In the literature, which is now fairly extensive, the following cases seem worthy of brief summary. Twiston Davies[10] gave thallium acetate to two sisters: F., aged 11 years, who received 8·5 mg. per kg., and M., aged 8, who received 8·75 mg. per kg. of body-weight. M.'s condition was normal throughout, and she epilated successfully, but F., although

she epilated normally, complained of pain in the knees on the twelfth day after the dose. By the sixteenth day the lower extremities were swollen, hot, and tender, with fluid in both knee-joints. A fit, followed by unconsciousness for two hours, occurred on the eighteenth day, and was succeeded by choreiform movements, with a temperature of 101° F. and acetonuria. A slow recovery was made in about one month. There was no history of epilepsy.

Fuld [11] reported a case in a boy of 12 who was given 8 mg. per kg. and who became ill two days later with pains in the lower extremities. No fit occurred, but he was in acute pain, lying in bed screaming, for some days. The acute illness lasted five or six weeks. During this time he suffered from diarrhœa, and four months later he was quickly tired, had a poor appetite, was easily agitated, and suffered from diarrhœa.

Bachkevitch and Prokoptchouck [12] reported a case of a man of 20 who received 8 mg. per kg. for favus. He was healthy, except for a slight enlargement of the thyroid. Albuminuria occurred on the same day, and by the third day he was ill with a temperature, rigors, difficulty in swallowing, and swollen and infected tonsils. He improved, and epilation commenced on the eleventh day. Fifteen days later he had a fit, and was excited, restless, and delirious; he bit his tongue. He developed a petechial eruption on face and neck. Owing to his excited state and to the development of hallucinations and delusions of persecution he was transferred to a mental clinic, but eventually made a complete recovery.

A somewhat similar case is reported by Peter, where a second dose was given because epilation after the first was not successful. Ritter and Karrenberg [13] report two cases where 8 mg. per kg. was given to two boys aged 6 and 5 years. About a week after the dose the whole mentality of the younger changed from that of a bright and happy child to that of a dull and tired child, and 15 days after the dose he developed a toxic rash with irritation. The hair subsequently grew very patchily and slowly. The elder brother's mentality changed in the same way and he had, in addition, a great deal of pain in the head. Epilation was never complete. One of us (J. M. S. S.) has heard of a similar case in this country.

Sir William Willcox has kindly supplied us with the following cases in which the epilating doses were repeated through a misunderstanding.

1. Two full epilating doses of thallium acetate were given at a week's interval to a child of 5 years. This was followed by nausea, collapse, and loss of consciousness for some hours. The child was subsequently ill with symptoms of peripheral neuritis, but eventually recovered.

2. Three full epilating doses were given at weekly intervals. Vomiting occurred after the third. The child was paralysed, but after some months recovered.

3. A child, aged 8, received two full epilating doses, but after some nausea and drowsiness recovered in 48 hours. As recovery was good a third dose was given. After the third dose drowsiness and coma developed. The patient remained in this state for several weeks and there was definite evidence of organic change in the basal nuclei. Nystagmus and squint and a double extensor response were present. The state of coma vigil persisted for some weeks, with low muttering delirium and incontinence of urine and fæces. The child improved but was found to be suffering from blindness and marked mental affection, but is, however, stated to be slowly improving.

FATAL CASES.

Accidental overdose has occurred on several occasions, and Buschke and Langer report a similar mistake to that in our series; the child received ten times the normal dose, and died in 24 hours. The most serious cases occurred in an orphanage in Granada. Here a large number of the children were affected with ringworm, and a dermatologist, having confirmed the diagnosis, decided to use thallium. Having no previous experience of the drug, he made the mistake of giving it to 16 of the older children of ages 7–14. This mistake, although likely to produce toxic symptoms, would not be expected to produce fatal results. They had the usual dose of 8 mg. per kg., and the drug was dispensed correctly, but the scales on which the children were weighed were afterwards stated to be inexact (to what extent is not stated). After three days the first child became ill and died the same night, and eventually 13 out of the 16 died, and at the time the account was written the remaining three were not expected to live. Although no details are available it seems likely that an excessive dose was given, but not one greatly in excess of the epilating dose, for many of the patients lived for about three weeks, whereas a large excess of the epilating dose kills in 24–30 hours.

Merkel [14] has described three fatal cases in which the children did not even receive their full epilating dose. The first case, 12 years old, was due to receive 0·336 g. (8·0 mg. per kg.), but actually received 0·033 g. every day for seven days—i.e., 0·233 g. On the seventh day he was taken ill with muscle pains, and he died six days later. The second case, 10 years old, was due to receive 0·196 g. (8·0 mg. per kg.), but received 0·03 g. daily for five days—i.e., 0·15 g. On the fifth day he was taken ill, and he died ten days later. The third case, aged 11 years, who had suffered from encephalitis, was due to receive 0·296 g., and actually received 0·2 g., taking 0·1 g. the first day and 0·033 g. on the three subsequent days. He was taken ill and died 14 days later. The post-mortem examinations on the three cases were described fully, but the only positive findings were extreme cachexia and lack of fat in all organs.

Accidental poisoning by thallium has occurred, and was not diagnosed until late in the illness. Ramond [15] reports that a young girl was taken ill suddenly with symptoms suggesting an acute abdomen, but no operation was performed. She became worse, with increasing abdominal pain and paralysis of the lower limbs; about a month later epilation gave the clue to the condition. For three months before the illness she had been in the habit of using on her face a cream for superfluous hairs which contained 2·5 per cent. thallium. Six months later she was still paralysed and the hair had not regrown. It is probable that sufficient of the cream had been swallowed to produce the symptoms.

Zelio-corn and zelio-paste containing 2·1 to 2·8 per cent. thallium are used fairly extensively as rat poisons in Germany, and have been responsible not only for accidental but also for a number of criminal cases. Greving and Gagel [16] record a case of a woman who attempted suicide by spreading about half a tube of the paste on bread and swallowing it. She was taken ill two days later with great pain and albuminuria. Epilation occurred on the twelfth day. The patient was ill for months with severe peripheral neuritis, tachycardia, pains in the chest, emaciation, achlorhydria, and amenorrhœa.

Haberda records two cases of murder by zelio-paste: the murder of a husband by his wife, and the murder of an infant by its mother. In the latter case an exhumation was made, and hyperæmia of the brain and fatty degeneration of the heart, kidneys, and liver were found. Kaps reports a case of murder in which the victim was given three tubes of zelio-paste in repeated doses. He became blind and died a few days later, the total amount of thallium given being about 2·25 g. Heuck and von Zumbusch have,

as a result of their considered experience, decided to abandon the use of thallium acetate.

Chronic industrial poisoning by thallium has been investigated by Buschke.[17 18] In a chemical works where thallium was isolated from pyrites residues the manager and five workmen fell ill after a few weeks' work, complaining of fatigue, loss of appetite, pains in the knees, and epilation. In all cases there was a marked eosinophilia and lymphocytosis. All improved on being removed from exposure to thallium, and in only one case did eye symptoms develop. (Details are not given, except that he was left with a posterior synechia of the iris.) In another factory employing six men, one man, after working for three months with thallium, showed double optic atrophy with loss of sight, eosinophilia, loss of knee-jerks, and lymphocytosis. Four men, after working two or three months, had albuminuria which, in spite of removal from exposure to thallium, remained chronic in two. These men also suffered from pains in the limbs and loss of hair. A third factory, where contact with thallium was only occasional, had no cases of poisoning, but some of the workers showed eosinophilia.

Conclusions.

As a result of these reports we are of the opinion that thallium acetate should not be used as an ordinary routine treatment for ringworm of the scalp. We have based this opinion on the following conclusions:—

1. Thallium in itself is a highly toxic substance showing a marked similarity to lead, both in its chemistry and in its toxic symptoms, and the far-reaching effects of the poison are much greater than is generally supposed.

2. It has a definitely selective action on all forms of nervous tissue, and it has been demonstrated that, even in infinitesimal doses, it causes slight degenerative changes in the brain cells of rats. It is therefore most unlikely to leave the human brain entirely unchanged, and it seems impossibe to be certain that it does not hinder further brain development.

3. The margin between an epilating and a toxic dose is extremely small and allows for no idiosyncrasies, whereas with X rays the dosage is very accurate, trouble is rare, and if a mishap occurs it is at least local.

4. Ringworm of the scalp is not in itself a fatal disease and, though often troublesome, can usually be cured by other means. It therefore does not seem justifiable to use such a powerful poison in an attempt to cure it a little more quickly.

5. It is quite easy to obtain thallium salts in a state of purity, and there is no especial reason why a solution which has been kept for some time should not be used. We do not believe that toxic phenomena were ever due to the use of an old solution.

Our thanks are due to Dr. W. Knowsley Sibley for permission to publish the three cases on which this article is based.

EXPERIMENTAL INDUCTION OF TUMOURS

WITH BLAST-FURNACE TAR.

By I. Berenblum, M.D., B.Sc. Leeds,

RILEY-SMITH RESEARCH FELLOW, DEPARTMENT OF EXPERIMENTAL PATHOLOGY AND CANCER RESEARCH OF THE UNIVERSITY OF LEEDS.

The present experiments are the outcome of some investigations which were originally undertaken to discover the reason for the failure of certain tars to induce tumours.

The prevalent view concerning the carcinogenic action of tars is that those which are capable of inducing cancer contain certain "specific carcinogenic principles" and, conversely, that those tars which are ineffective are deficient in such principles. In a previous communication [1] an alternative explanation was suggested. It was found that an actively carcinogenic gas-tar could be almost completely prevented from inducing tumours by the addition of 0·1 per cent. dichloroethyl sulphide (mustard gas) to the tar, and that the inhibition was due to some action of the mustard gas on the animal, and not to any alteration of the constituents of the tar itself. These results suggested that the presence in certain tars of substances with an inhibitory action similar to that of mustard gas might be responsible for the failure of such tars to induce tumours. In other words, a particular tar might appear to be non-carcinogenic not because it lacked those constituents which were responsible for the induction of tumours, but because the carcinogenic action of those constituents was masked by the additional presence of inhibitory substances.

In the present investigations it was proposed to test this hypothesis, using an extract of a blast-furnace tar as an example of a non-carcinogenic tar. The experiment proved unsuccessful, because this extract of blast-furnace tar, which was assumed to be non-carcinogenic, actually produced tumours when applied to the skin of mice. Up to the present blast-furnace tar has always been considered to be entirely lacking in the power of initiating tumour growth, this view being based on both clinical and experimental evidence. Although epitheliomatous lesions of the skin are not uncommon among the workmen in the gas-tar industry, no such lesions have been observed among those who come into daily contact with blast-furnace tar (Legge [2]). There is no record at the Home Office of a case of epithelio matous ulceration from blast-furnace tar, although 520 (with 79 deaths) have been reported from pitch and tar in the ten years 1920–29, and the total from pitch, tar, paraffin, and oil during the same years was 1151, with 296 deaths (Bridge [3]).

In 1923 Leitch [4] tried the effect of a Scottish blast-furnace tar on the skin of mice and, although the treatment was continued for eight months, he failed to induce a single tumour. Kennaway,[5] studying the

carcinogenic action of different tars and tar fractions in great detail, also maintained that blast-furnace tar was free from carcinogenic action. Though emphasising the differences between the mode of production and chemical composition of gas-tar and blast-furnace tar, he concludes that "it is uncertain whether the inability of blast-furnace tar to produce cancer is due to the nature of the coal, to the temperature of carbonisation or to some reaction which is dependent upon the peculiar chemical conditions in a blast-furnace." In the most recent communication dealing with the subject, Kennaway and Hieger [6] state once again that blast-furnace tar is not carcinogenic, but they do not mention whether this statement is based on Leitch's original experiment or whether it is an outcome of similar experiments performed subsequently by themselves.

FIGS. 1 2 3 4

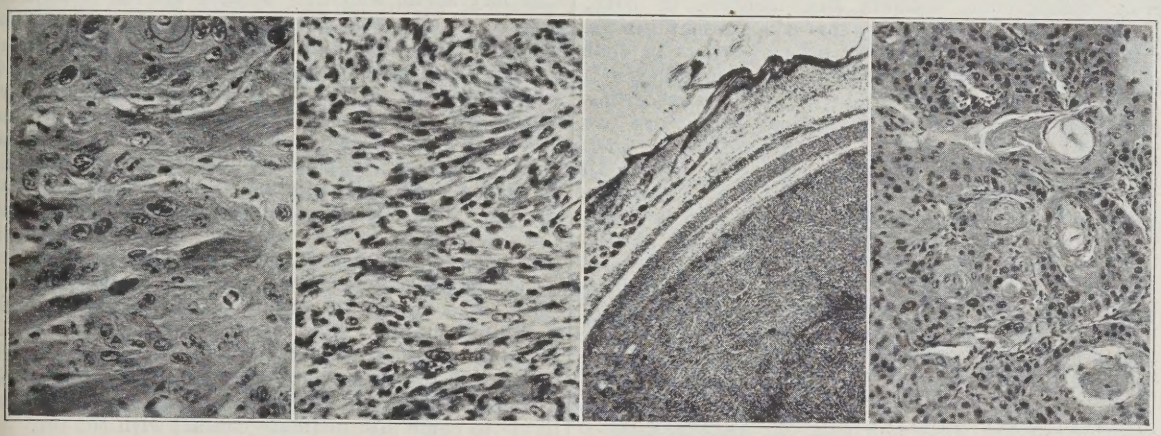

FIG. 1.—Mouse 74M5, painted with an ether extract of blast-furnace tar for 30 weeks. A squamous carcinoma, showing invasion of muscle. (× 220.)

FIG. 2.—Mouse 87Ma, painted once a week with the untreated blast-furnace tar for 18 weeks. A spindle-cell sarcoma. (× 225.)

FIG. 3.—A low-power view of the same tumour (Fig. 2), showing muscle between the tumour and the skin. (× 27·5.)

FIG. 4.—Mouse 91M3, painted twice a week with the untreated blast-furnace tar for 35 weeks. A squamous carcinoma. (× 115.)

Tumours Produced by the Tar.

In view of all this evidence in support of the contention that blast-furnace tar is non-carcinogenic, the discovery that an extract of such a tar could lead to the development of tumours in mice called for a more searching inquiry into the problem. Consequently, I decided to follow up this original observation, leaving aside the wider problem which I at first set out to investigate.

In the original experiment, 45 mice received weekly applications of an ether extract of a Scottish blast-furnace tar, which was prepared in the following manner. A simple ether extract of the tar was dried and treated with lime. This mixture was extracted once again with ether, the ether was evaporated, and the residue was employed for application to the skin. This ether extract was applied to a small area of skin in the dorsal region, the hair covering that area being cut short with a pair of curved scissors before each application, thus obviating the use of a chemical depilator.

Warts began to develop from the twentieth week of tarring, and, by the forty-fourth week all the surviving animals had acquired tumours. Altogether, out of the 45 mice which were originally subjected to the tarring, 25 developed tumours. On histological examination, seven of these tumours were found to be malignant. A photomicrograph of one of these is shown in Fig. 1.

The fact that an ether extract of the tar, after preliminary treatment with lime, was used in this experiment precluded me from declaring that the original tar itself was carcinogenic. It was possible that the chemical treatment might have been responsible for this action. It was necessary, therefore, to repeat the test, using the original untreated tar instead of the ether extract. This was carried out in the following experiments.

Fifty mice received weekly applications of the untreated tar, the procedure being otherwise the same as in the previous experiment. Unfortunately, the mortality was very high, but, in spite of that, five of the animals developed tumours. Four of these tumours were simple warts and the fifth was a spindle-cell sarcoma which developed under the treated area of skin, beneath the panniculus carnosus (Figs. 2 and 3). The last experiment was repeated, this time using 100 mice and applying the untreated tar twice a week. After 38 weeks 21 mice had acquired tumours. Nineteen of these tumours remained simple warts, whereas two developed into squamous carcinomata (Fig. 4).

The results of all three experiments are given in the accompanying Table, together with some results of a similar experiment with a known carcinogenic gas-tar.

The only conclusion is that the sample of blast-furnace tar used in these experiments, though not

as potent as gas-tar, is definitely capable of inducing tumours in mice. The discrepancy between these results and those obtained by previous workers suggested at first that the tar used in the above experiments was not a true sample of blast-furnace tar. It was, therefore, decided to obtain more accurate information about the tar as regards both the method of its production and its chemical composition.

Source of the Tar.

The blast-furnace tar was obtained from an iron works in Scotland. It was made from a battery of furnaces which were employing a mixture of approximately 88 per cent. splint coal and 12 per cent. coke. It has been frequently stated in the literature that Scottish blast-furnace tar is produced from splint coal, without any mention of coke. It would appear, therefore, that the present sample differed from those used by other workers in that coke was added to the splint coal in its manufacture. However, after consulting different authorities, including several ironworks where such tars are produced, it appears that the addition of a small percentage of coke to the splint coal is the rule in all Scottish blast-furnaces, and that this has been the practice for at least the last 20 years. To satisfy myself still further that the tar used in my experiments was an authentic example of blast-furnace tar, it was submitted to fractional distillation by Mr. H. D. Briggs, of the Yorkshire Tar Distillers, Ltd. The result of the analysis was as follows: 52 per cent. water, 6 per cent. naphtha, 20 per cent. light and heavy oils, 22 per cent. pitch. The report concluded with the statement: "This sample seems a true blast-furnace tar, but there is a large quantity of water." The presence of an excess of water (of which a certain amount is always present in blast-furnace tar) could not be held responsible for the carcinogenic action. It is therefore possible to induce tumours in mice with a genuine sample of blast-furnace tar, and, furthermore, blast-furnace tars in general can no longer be regarded as non-carcinogenic, though admittedly other samples may be inactive.

The fact that gas-tar and blast-furnace tar are both carcinogenic, despite the differences in their chemical composition, the nature of the fuel used in their production, the temperature of carbonisation, and the conditions of the respective distilling plants, must be considered of some significance, particularly in relation to the controversy on the "specificity of carcinogenic agents."

These results may also be of interest from the industrial aspect. So far no case of skin cancer arising from contact with blast-furnace tar has ever been reported. The workmen in the ironworks from which the present tar was obtained have been examined by a medical inspector of factories, and no case of epitheliomatous ulceration was discovered. It is possible that blast-furnace tar, though sufficiently potent to induce tumours in mice, may not be capable of having any effect on man. Even if it be assumed that any agent which is carcinogenic for mice must also be carcinogenic for man, it would still not be justifiable to presume that, because mice are susceptible to blast-furnace tar, therefore the workmen who handle that tar should necessarily develop cancer of the skin. It is possible that the workmen do not handle the tar sufficiently frequently or for a sufficient length of time for the condition to develop, particularly as blast-furnace tar appears to be less potent than gas-tar. At the same time, it must be realised that the regulations dealing with the necessary hygienic measures and medical inspection are by no means as strict for blast-furnace tar workers as they are for those who come into contact with gas-tar, pitch, paraffin, and oils. Therefore it is not unreasonable to imagine that, as a result of more careful medical supervision, cases of cancer due to blast-furnace tar might yet be found in those industries in which workmen are liable to come into intimate contact with the tar.

The tar extracts have been prepared in the biochemical laboratory of this department under the direction of Dr. H. J. Channon, to whom I am greatly indebted. I should also like to express my thanks to Mr. H. D. Briggs for the chemical analysis of the blast-furnace tar.

CLINICAL AND LABORATORY NOTES

HÆMATEMESIS AS A SYMPTOM OF GASTRIC OR DUODENAL ULCER.

BY BASIL HUGHES, D.S.O., M.B. CAMB., B.SC. LOND., F.R.C.S. ENG.,
SURGEON TO BRADFORD MUNICIPAL GENERAL HOSPITAL; HON. SURGEON TO BRADFORD CHILDREN'S HOSPITAL; HON. ASSISTANT SURGEON TO BRADFORD ROYAL INFIRMARY.

SOME 20 odd years ago I was asked to see a man, 42 years of age, who was suffering from profuse hæmatemesis. He gave a very vague and unsatisfactory history of indigestion which did not fit in with the classical symptoms of either gastric or duodenal ulcer and unfortunately I was persuaded to operate upon him. I found no evidence whatever of gastric or duodenal ulcer and so the surgical history of this case finishes. This man is alive to-day and has had several gastric hæmorrhages since. Curiously enough, within the last year I was called to see his brother, who had suffered a severe hæmatemesis. He also had suffered from indigestion, which took the form of a discomfort only after meals. Examination revealed an enlarged spleen and a blood examination confirmed one of the primary anæmias. The day after the blood examination he sustained a fatal hæmatemesis.

During the last twelve years I have operated upon five cases for severe hæmatemesis and in only two of these cases was operation justifiable, for in three of them, despite the classical symptoms of duodenal ulcer, no ulcer existed, but the liver showed cirrhotic changes. In the other two cases there was a crater-like ulcer on the posterior wall of the stomach which was fixed firmly to the pancreas. Partial resection of the stomach was performed, but there was no evidence that hæmorrhage had occurred from the ulcer. It had taken place from numerous points in the inflamed tissues surrounding the ulcer, and again the liver was cirrhotic.

In nearly 25 years' experience I can only recall two cases of true hæmorrhage from an ulcer. Both patients died before surgical aid could be of avail, and post-mortem examination showed an erosion of the splenic artery. So far these findings fit in tolerably well with continental findings. I have encountered

in consultation, as one is bound to do, many cases of hæmatemesis in which the history and symptoms cannot satisfactorily be correlated with gastric or duodenal ulcer and which, in the quiescent periods, are negatived both by fractional meal and radiological findings.

Such experience shakes one's faith in hæmatemesis as a trustworthy symptom of gastric or duodenal ulcer, yet text-books still proclaim it and students are still taught it. If it is a symptom, it is a very rare symptom; such are my surgical and post-mortem findings. My own experience leads me to believe that hæmatemesis is a symptom that calls for the physician, for it has proved far more often the symptom of a medical rather than a surgical ailment. A surgeon friend of mine told me that he had operated upon a patient with hæmatemesis. He found a cicatrix at the pylorus and performed a gastro-enterostomy. An uncontrollable hæmatemesis followed and there was hæmorrhage from the operation wound. The patient died. There was no blood examination, but I feel sure this was a physician's case. Such conditions as hepatic cirrhosis, primary anæmias (insidious as they are), purpura (gastric epistaxis was not unknown in the near East during the recent war when purpura was prevalent), and other blood conditions must be excluded before a surgeon is asked to interfere.

A wise surgeon will always take a competent physician into his confidence before he operates upon a case of hæmatemesis.

A CASE OF SEVERE LEAD POISONING FROM DRINKING WATER.

By Norman Lorraine, M.D., D.P.H., F.R.S. Edin.,
MEDICAL OFFICER OF HEALTH, BENFLEET.

There appears to be no doubt that the following ase was one of severe chronic lead poisoning, due to lrinking water derived from a well which contained dangerous amount of lead.

The patient, a childless married woman aged 33, came to ve in the district in February, 1927, occupying a new ouse. Seven months later she had a three months' mis-arriage and felt out of sorts. In June, 1928, she was perated on in London for cystic ovaries, both being involved. n September, 1928, she went to Cumberland for six weeks nd felt much improved. Returning home, she again felt out of orts and decided to go to Cumberland for some length of me. By this time she had swelling of the arms, legs, and ngers, was losing weight considerably, and was suffering om anæmia to such an extent that for about seven weeks ie was confined to her bed and bedroom, but definitely nproved during her stay in the north.

In March, 1929, she returned home and very soon after-ards began to feel ill, being admitted to a local hospital July, 1929, suffering from loss of use of fingers and hands, id a certain degree of loss of use in legs and feet, extreme næmia, amenorrhœa, and marked loss of weight. She mained in hospital for about thirteen weeks. The impair-ent in use of fingers came on gradually about June, 1929, ginning with the little fingers of both hands, the right ing more involved than the left. The feeling of numbness read from the little finger to the other fingers of both nds. On her discharge from hospital she returned to her use and became more anæmic, emaciated, and undoubtedly riously ill. She was a lemon-yellow colour and suffered m severe constipation, colicky pains in the abdomen, a ling of sickness, and wrist-drop in both arms.

She was admitted to a London hospital at the end of ril, 1930. On her admission she was found to have nctate-basophilia. At the beginning of June, 1930, lead s definitely present in her urine, but her power of extension the wrist showed no improvement, although her general alth certainly became better. She still has dropped wrists d is very anæmic and constipated; her weight has pped from 9 st. 10 lb. to 6 st. 3 lb., and she complains tingling of the fingers, her hands showing trophic changes d flaccidity.

NATURE OF WATER-SUPPLY.

The domestic water-supply which, in my opinion, is responsible for her condition has its source in a surface well. The lead contained therein appears to be due to a plumbosolvent action of this water on the pipe system, which is lead.

An analysis of a sample of this water reports: "This is an exceedingly hard acid water containing a very excessive and dangerous amount of lead, practically all of which is in solution. Organically and bacteriologically the water is of a satisfactory degree of purity, but the amount of lead present is such as to render the water unsafe and unfit for drinking and domestic purposes."

I am indebted to Mr. E. C. Bilham, chief engineer to Southend Waterworks Company, for the following note: "The water referred to is drawn from shallow wells sunk in the sand and gravel—glacial deposits of the pleistocene period. The soluble salts in water drawn from these deposits vary greatly in different localities, and as these recent deposits include nearly all cultivated land, the water they absorb is markedly affected by manures and subject to surface pollutions; in addition, they are frequently very hard. These waters not infrequently act vigorously on lead, especially if they contain much carbon dioxide in solution. The presence, however, of silica as an alkaline silicate retards the action, and if the silica present approaches 1 part per 100,000 action is either entirely prevented or only occurs to a sufficient extent to coat the lead with a practically insoluble silicate which prevents any further oxidation and consequent danger from lead poisoning. The suitability for domestic purposes of water drawn from surface wells should always be regarded with suspicion until both chemical and bacteriological examination has shown the supply to be pure and wholesome."

I would refer those interested in the public health law aspects to Sects. 62 and 70 of the Public Health Act, 1875, and the Public Health Water Act, 1878, Sect. 3.

I should like to take this opportunity of thanking Dr. J. E. Jameson for the assistance he has given me in the investigation of this case.

ABDOMINAL TORSION OF OMENTUM.

By Douglas Robb, M.D. N.Z., F.R.C.S. Eng.,
ASSISTANT SURGEON, AUCKLAND HOSPITAL, NEW ZEALAND.

The paper by Mr. M. J. Smyth in The Lancet of Sept. 13th prompts me to record this case, which closely resembles several of his cases, and which falls into his class of pure intra-abdominal torsion of omentum.

A woman, aged 50, was admitted to Auckland Hospital on May 1st, 1930, complaining of abdominal pain of four days' duration. The pain was on the right side, and stabbing in character. It had been intermittent but became continuous and more severe six hours before admission. She had anorexia, but no vomiting. Her bowels were regular, and she did not suffer from dyspepsia. She had had a severe attack of right-sided abdominal pain with diarrhœa and vomiting one month before. She had borne three children.

Examination.—Temp. 97·6° F., pulse-rate 100, respirations 18. A stout woman in some distress. Tongue coated. Nothing abnormal was found in the chest. The abdomen was generally tender, but the maximum tenderness was found in the right iliac fossa and just above it. No definite rigidity could be made out. No mass was felt. A diagnosis of acute appendicitis was made, and immediate operation carried out.

Operation.—Under general anæsthesia the abdomen was opened by a median pararectal incision below the umbilicus. A little blood-stained fluid escaped on opening the peritoneum. The appendix was found to be normal. On further exploration a purplish irregular mass of omentum, half the size of a closed fist, was found arising from the transverse colon near the hepatic flexure. It had become twisted 540 degrees in a clockwise direction on its pedicle. It was not adherent to any other structure. The twist was undone, the pedicle transfixed and ligated, and the mass removed. The abdomen was closed as usual.

Progress was uneventful until the fourteenth day when the patient reported a sudden sharp pain in the right side of the chest. The temperature reached 99° on the next two days. The trouble soon subsided, and she was discharged well on the twenty-fourth day. The pain was attributed to a small pulmonary embolism.

I am indebted to Mr. Kenneth MacCormick for permission to publish these notes.

CENTRAL ASSOCIATION FOR MENTAL WELFARE.

CONFERENCE IN LONDON.

A CONFERENCE organised by the Central Association for Mental Welfare was opened on Dec. 11th by the Minister of Health. The chair was taken by Sir LESLIE SCOTT, and the subject of discussion was developments in mental health work under the new Act. At a luncheon held in the Hotel Russell Mr. L. G. Brock, chairman of the Board of Control, was the guest of honour; he also took the chair at the afternoon session, when there was a discussion on

Social Services and Mental Hospitals.

The CHAIRMAN said that the social worker might be looked upon as the expert assistant of the psychiatrist or as the friend of the patient; although the two rôles were not necessarily incompatible, views on the training required would depend on which rôle was under consideration. He thought it possible to overemphasise the necessity for prolonged training; it was essential to get the right type of worker, one on whom the patient would look as a friend. From the patient's point of view the untrained voluntary worker might be more acceptable than the professional. Efficiency was less vital than sympathy. There was a wide scope for this type of worker inside the mental hospital. The Board of Control had no wish to see any uniform organisation rigidly enforced all over the country; the scheme must be adapted to local conditions.

Dr. THOMAS BEATON said that the central point of the social service would be the clinic, and that the mental hospital was but one of its side issues. In mental or nervous disorder the whole life situation of the patient was most closely bound up with the illness, and a survey of the life and environment of the patient was an essential part of the history, as a change in environment was often an essential part of treatment. The clinic must be run as a public utility service; it was not merely a medical matter, but dealt with every kind of sociological problem. No doctor could undertake the work without social assistance. The whole scheme should be under the supervision of the superintendent of the mental hospital, and comprehensive records should be kept. A close liaison must be maintained with the probation service, the school medical service, child welfare centres, and other social services. A hundred and one details needed attention, and the only satisfactory source of the necessary help was either a specific department under the local authority or else the mental welfare association. The Mental Treatment Act and the Mental Deficiency Acts must essentially be worked together. In time the mental health service would become one of the most important factors in the well-being of the community. The best training for the voluntary worker was a practical one. The ideal worker would know nothing whatever of psychology; she would sit in the clinic and listen, her business being to note facts and not to express an opinion. No matter how difficult the problem, something had to be done to help the patient.

The Training of the Social Worker.

Miss ST. CLAIR TOWNSEND discussed the types of patient likely to benefit by social service: unstable children and adolescents and adult cases of "breakdown"; patients in mental hospitals or observation wards; and those discharged or on licence. The worker should be experienced in general social work and have had a specialised training in child guidance mental deficiency, and work for adults. There was now a year's post-graduate course at the London School of Economics. It was most important that after-care should be in the hands of the same worker as had become a friend of both patient and relatives while the former was in hospital. Although the requisite attributes of character sounded ideal—tact balance, patience, humour, and receptiveness—all of them, save perhaps humour, could be acquired through training and experience. Without training the most gifted person could not be the right kind of worker. In America they felt that the use of untrained workers had been harmful to the work. Any scheme evolved should be unitary and elastic and should ensure continuity.

Dr. G. W. JAMES described the history and work of the Mental After-care Association, and illustrated the imperative need for skilled guidance on discharge from mental hospitals, and the invaluable prophylactic help afforded by the Association in out-patient departments. After-care and pre-care work of this kind was of the utmost value. He agreed with Miss Townsend that a certain amount of training was essential; women did the work very much better than men. The worker should spend some months in the almoner's department of a general hospital, should be familiar with mental hospitals of every type, and with child guidance, and should have experience of some sort of general social work, such as the Charity Organisation Society. He agreed with Dr. Beaton in praying that the social worker be delivered from a knowledge of psychology. It was more important for a home visitor to know the names of the children than the name of some complex that might afflict the mother.

Dr. A. A. W. PETRIE urged the importance of a unified service including both normal—as in child guidance and the problem of the social inefficient—and abnormal. The problem extended from the mild neurotic to the psychotic for whom institutional care was inevitable, and in every grade the psychiatrist needed the help of the social worker, on whom the success of the out-patient department largely depended. He thought the general sense of the doctor and other workers could be trusted to deal with or get rid of the person who dabbled in psychology. He stressed the importance of personal contact between social worker and medical staff. By the prevention of mental disorder the social service would stand or fall, and in intelligent prevention lay the hope of advance in mental hygiene.

Dr. LETITIA FAIRFIELD said she had been bewildered to hear a distinction drawn between efficiency and sympathy, and had only understood it on hearing that women were better than men at the work. The male sex always thought women were using tact and sympathy and womanly charm when they were using sheer hard experience and training. The poor appreciated more than anyone the value of efficiency; no one was more cordially disliked in the homes of the poor than the merely sympathetic person. Associations that made a success of home visiting owed their success to the fact that their workers were willing to undergo hard practical training. This was an extremely difficult and highly technical job and must be learnt by anyone who was to be of any value either to doctor or patient. The individual who had been to a few popular lectures or read a few popular books on psychology was to be dreaded, but the training in psychology given at the London School of Economics course, for instance, was not to be

deprecated. The success of the Act would depend very largely on the social service. Without it the clinic was likely to be much more interesting for the doctor than useful for the patient.

A brief discussion followed.

On Friday morning the chair was taken by Mr. R. C. MORRISON, K.C., and Dr. E. O. LEWIS read a paper on

Ascertainment of Mental Defectives.

He said that ascertainment was looming large in the activities of local mental deficiency authorities at the present time. The numbers were so great that, even when the local authority had made adequate colony provision for the younger defectives, there would still be considerable need for accommodation in institutions for older defectives, and those in receipt of outdoor relief should be ascertained in order that they might attend occupation or handicraft centres. The defectives living in the general community presented considerable difficulty; the criteria for determining the kind of care they needed were hard to fix. It was no exaggeration to say that the retarded children were the most neglected group in the educational system. Cöoperation between the education officer and the school medical officer was essential, and the best person to make a survey was the educational psychologist. He thought that a survey to estimate the retarded children in a school population of 10,000 could be made in three or four months at a cost of about £400. The Wood report had estimated that there were nearly 9000 imbeciles attending day-schools, doing great harm both to themselves and to the system.

Mrs. HESTER ADRIAN read a paper on guardianship. Dr. Lewis's recent inquiry, she said, had estimated that about 80,000 defectives could be left in the community. These would not all need the same amount of care, control, or training. The four forms of community care available were voluntary supervision, statutory supervision, guardianship, and licence. Voluntary supervision, the most lax of the four, could be applied, Dr. Lewis had estimated, to rather more than half the cases. Statutory supervision was particularly suitable for low-grade cases in satisfactory homes who needed training. The chief difficulty in the way of guardianship was the stringency of the regulations, which alarmed parents and foster-parents; this might be overcome by making the local authority the statutory guardian, with a guardianship officer to select foster-parents and supervise them. Guardianship in this form would differ very little from licence and might be more popular. Suitable guardians could be found if carefully sought, and many difficulties could be overcome by unity of control and coöperation between all bodies concerned; a full-time guardianship officer should be appointed where possible.

A discussion followed.

On Friday afternoon the chair was taken by Sir BASIL BLACKETT, and Dr. LANGDON-DOWN spoke on the need for an inquiry into the

Causation and Prevention of Mental Deficiency.

He pointed out the drawbacks of a Government inquiry as a form of machinery for inquiring into this subject; it was a lengthy process and legislative measures followed it but slowly. He maintained that the Wood report showed that the problem of mental deficiency was thoroughly understood in its main aspects and justified cautious progress on the lines suggested. Everybody was agreed that it was undesirable for defectives to become parents, and the proposal made by those in favour of sterilisation was that it should be made lawful for medical practitioners to carry out sterilisation, with consent, under proper safeguards. This facility need not await a further inquiry, did not obviate such an inquiry, and might well lead to the provision of valuable evidence. It was an essential step before any further advance could be made. In the cases for which sterilisation was advocated, ordinary contraception methods were inapplicable. Both the Wood report and the last report of the Board of Control had spoken of sterilisation as advantageous in certain cases. Who was to say that the effect of cutting off at the source even a few families of defectives would produce no appreciable result in the long run? Surely the time had come to seek the power to use one of the admitted modes of stemming the "racial disaster" of mental deficiency. Proof of the results of sterilisation could only be obtained as the result of trial, and such trial could only be made when the procedure was sanctioned by law. Whereas sterilisation was a real preventive of procreation, the regulation of marriage and safeguarding were not. Sterilisation was not, of course, anything but a supplement to segregation; it would be particularly useful for higher-grade defectives and those sent home on long licence. Dr. Langdon-Down hoped that the facility would be granted without awaiting the outcome of another inquiry.

Dr. C. P. BLACKER supported the plea for sterilisation, and said that the whole problem touched upon delicate preconceived opinions. Any investigation would therefore have to be very thorough and its results absolutely above suspicion if unanimity were to be attained. It would therefore take a long time. If the prevention of feeble-mindedness were to be taken seriously some steps must be taken to limit the fertility of the "social problem" group—one-tenth of the population of the country. To this group segregation, regulation of marriage, and birth control were inapplicable; sterilisation was the only method. At present the group resorted to an enormous extent to abortions; the possible effect of abortifacient methods on the production of secondary amentia was worth consideration. The child was very likely to be affected by poisons, interference with blood-supply, or direct pressure. Sterilisation would thus be a measure of prevention for secondary as well as for primary amentia. The experience of birth control clinics suggested that numbers of the social problem group would avail themselves of sterilisation; at present it was extremely difficult, if not impossible, to obtain sterilisation for a patient who could not afford to pay, though easy for those who could. The last thing the Eugenics Society wanted to do was to plunge into legislation which would subsequently have to be withdrawn; it wanted to get the thing going on a very small scale to obtain some results to study.

ARGUMENTS AGAINST STERILISATION.

Dr. A. F. TREDGOLD argued the point of view of those who wanted a full and careful survey of the subject before anything was done. Mental deficiency, he said, would not be appreciably reduced in extent or cost by sterilisation; only a small proportion of defectives were produced by defective parents—about 5 per cent., he thought, but nobody knew, and knowledge on this point was the crux of the whole question. He protested against the way in which the public had been misled on this matter. A reduction of 5 per cent. might be better than nothing if it could be obtained without risk, but in the present

state of our knowledge the risks were too great. It was hard to select the case suitable for return to the community; there was a very real risk of promiscuity and spread of venereal disease among girls in villages and small communities if they were known to be sterile; it would be very difficult to frame regulations; there would be a danger, if sterilisation were legalised, that local authorities would attempt to use it to save the expense of institutional accommodation; legalisation of sterilisation might well delay rather than hasten the solution of the problem, for the general public would think it had been solved. Mental deficiency was the final manifestation of a pathological change in the germ plasm brought about by environmental influences, but the change did not always cause mental defect. We knew little about the factors responsible for the germinal change, and could not recognise carriers. If every defective and carrier could be eliminated to-day a new crop would soon appear.

Dr. F. C. SHRUBSALL pleaded for a thorough investigation into the proportion of the feeble-minded who could be said with certainty to be cases of secondary amentia. A full family history from the grandparents downwards would give a great deal of information about the methods of inheritance of deficiency. The standard of mental efficiency had risen with standards of living and custom; it was important not to label as deficient those who were only examples of a lower grade of culture. It was extremely difficult to get hold of a defective; the penalties on parents were seldom enforced. Confusing talk about sterilisation would only hinder the ascertainment officer in his work. The higher the grade of the defective the more difficult it would be to conduct a case if it became known that certification might convey a risk of subsequent sterilisation. He feared the effects of premature action. It would be no gain to the nation to sterilise 100 defectives a year and lose 200 or 300 who might have been segregated. It was essential to have public opinion behind any attempt at legislation. A commission or committee might ensure that opinion.

Dr. F. D. TURNER said that nothing whatever was known about the causation of mental deficiency. Genetic experiments on flies were not applicable to human beings. It seemed impossible that the hotch-potch of conditions known as mental deficiency could be due to a single cause. Some authorities held that hardly any mental defect was due to heredity, and in Denmark they had come to the conclusion that 80 per cent. was due to preventable causes. At his own institution Dr. Turner had found that only 2½ per cent. in each generation was due to direct inheritance. It was easy to blame heredity instead of doing what could be done to alter preventable causes. Fifty per cent. of amentia could probably be prevented with a little more public health knowledge. He agreed with Dr. Tredgold that any measure of sterilisation would only prevent the careful inquiry that the subject needed, and with Dr. Shrubsall that the Eugenics Society spoke with two voices. He admitted that a few defectives were detained in institutions only because of the fear of their having children, but it was less than 1 per cent. Cases came back from licence through sheer failure to get on in the world. He was convinced that a sterilised defective girl would find it almost impossible to be moral. Any measure of sterilisation would prove the thin end of the wedge. In America it was becoming merely a means of hitting anyone you did not like.

Dr. H. B. BRACKENBURY argued in favour of the appointment of a committee or commission. He did not regard such a body as a suitable implement for research, but thought it would do something which ought to be done: gather together information and set it forth in an authoritative manner. The latest knowledge on deficiency and heredity should be collated and set forth. The general public knew practically nothing, and even the interested intelligent section were largely speaking in the terms of ten years ago, so great had been the recent advance in this field. He put some questions which he would like the commission to answer. What was the common level of intelligence in the population to-day? Most people placed it too high, and on the answer to this question depended the definition of mental deficiency. How far was it true that the families of defective parents tended to be larger than the average? This was a legend that seemed to have little foundation. Did that proportion who could be trusted in the community behave themselves socially and sexually in as decent a manner as the rest of the population or not? On what lines could genetic experimentation take place? He no longer agreed with those who wanted to legalise sterilisation as a preliminary step.

Mrs. C. B. S. HODSON said that Punnett's figures on elimination of defect by sterilisation were based on a number of facts no longer accepted, and Fisher's corrections had shown that there would be a decreasing elimination, complete elimination being put off for hundreds of generations. Recent Continental figures and pedigrees showed that deficiency was of many kinds depending on many factors, but that certain of these factors were dominant, not recessive. This made the prospect of elimination much more hopeful.

Mrs. NEVILLE ROLFE did not think that venereal disease would be increased by sterilisation. In California it had not, because the social care had been continued. Sterilisation could never be an alternative to social care; it seemed to be assumed that the public in this country was too stupid to realise this, but she questioned whether we were so unintelligent. A great problem was the amount of defect propagated by high-grade classes not under social care.

Father J. B. BAGSHAWE said that the Catholic Church regarded the prevention of procreation as a grave sin, the guilt of which must be shared by everyone concerned in the operation. The Catholic body in the country would oppose the Bill by every means available. He was sure that the measure would defeat its own object.

Dr. BLACKER, in reply, emphasised again that the advocates of sterilisation did not regard it as a "solution"; the problem would never be solved. Much about human beings had been learned from animal experiments; Mendelian ratios, for instance, extended right through the animal and plant world. If two-thirds of the defective population were to live in the community, sterilisation might be a useful adjunct to social care.

PAYMENT OF A HOSPITAL STAFF.—In consequence of a request by the medical staff of the Malton, Norton, and District Hospital that they should be paid for their services, the monthly board has prepared rules which require that both subscribers and non-subscribers shall pay for medical attendance, except in proved necessitous circumstances. The request was made because patients who could afford to pay refused to do so, and took advantage of free treatment not intended for their benefit. A scale of charges is to be fixed in consultation with the medical staff, but the new arrangement is subject to the sanction of the annual meeting of subscribers.

REVIEWS AND NOTICES OF BOOKS

Modern Psychotherapy.

By EMANUEL MILLER, M.A. Camb., M.R.C.S. Eng., Honorary Psychopathologist, West End Hospital for Nervous Diseases; Psychiatrist, Child Guidance Clinic of the Jewish Health Organisation, London. London: Jonathan Cape. 1930. Pp. 131. 5*s*.

Dr. Miller has tackled an extremely difficult problem courageously and with a considerable measure of success. He surveys first the general principles of psychotherapy and of the chief methods used, including the three leading schools of analysis, hypnosis, suggestion, auto-suggestion, and persuasion. He manages to give a very fair account of each of them, despite the innumerable pitfalls that await the feet of anyone who tries to be eclectic in these matters. Freudians may, perhaps, feel that the importance of the pregenital or polymorphic stage of sexuality is somewhat lightly sketched and the followers of Adler—at any rate in this country—may complain that insufficient stress is laid on the principle of studying the individual as a whole, from every possible angle. A certain amount of bias on the philosophical side of Jung's teaching is inevitable, seeing that the Zürich school has written practically nothing about its practice. The suggestion, however, that the "pill" presented to the patient of Jung is any less bitter in practice than that offered to the patient of Freud, or that in practice the Jungian physician ever attempts to direct the patient's path from a "Pisgah height" will hardly be acceptable to members of this school. Any salvation that is to be of any use must inevitably be found by the patient himself, as Dr. Miller recognises in his criticism of the "short-cut" methods of hypnotism and suggestion.

The chapter on the application of psychotherapy inevitably leaves the reader with the feeling that a book on this subject for the general practitioner has yet to be written. Dr. Miller's guide-posts are undoubtedly useful, but they leave much unsaid. There is all the difference in the world between the position of the practitioner who has read this book and that of one who has read a corresponding book on, say, some recent development in surgical technique. In the latter case he is not only told the history and present position of the technique; he is—or can be—also told just how and how far he can apply it himself and what cases should be referred to a specialist. Perhaps it is impossible to perform this service for psychotherapy at the present time, and for two reasons. One is that many psychotherapists are too devotedly wedded to their own particular theory and method; the earlier part of this book shows that Dr. Miller at least is not one of these. The other is that British practitioners in general lack any elementary background on which an author could build. In many American medical schools students are taught psychology by lecture, and are required to make a character study of their own personality and emotional trends and a detailed investigation of one patient, apart from the usual out-patient and ward teaching in psychological medicine. On such a foundation can be built post-graduate instruction which will be really helpful. The practitioner of the future will, we trust, be taught how to anticipate and prevent just those conditions which Dr. Miller lists as suitable cases for psycho-therapeutic treatment. Meanwhile his book marks an important advance. He writes clearly and simply, and has compressed a great deal of information into a handy little volume which will be of interest to practitioners and psychotherapists alike.

Laboratory Medicine.

By DANIEL NICHOLSON, M.D., M.R.C.P., Assistant Professor of Pathology, University of Manitoba. London: Henry Kimpton. 1930. Pp. 433. 28*s*.

THIS book differs from most manuals on clinical pathology in that the author makes a real effort to explain the rationale of and therefore the indications for the various diagnostic procedures which he describes. To give a complete and reasoned explanation of all laboratory diagnostic procedures would require a bulky treatise covering most of the field of general medicine, medical bacteriology, and pathology. The author has used great skill to get as much information as he has into 433 pages; in fact so well has he succeeded that a danger arises that the reader may regard his book as containing all the pathology that he need know. The work is up to date and contains descriptions of many procedures which have not previously found their way into text-books. The use of the blood groups in the determination of non-paternity is described; simple rules are given for the estimation of the basal metabolism rate, and sections are devoted to the collection and use of human immune sera against poliomyelitis and measles. A useful section is that describing Terry's method for the rapid diagnosis of histological sections, which has hitherto only been available in this country in the columns of the *Journal of Pathology and Bacteriology*. In the section on blood transfusion the author perpetuates the old superstition that even when matching has been performed the determination of the group of donor and recipient is still necessary; his statement five cells per c.mm. constitutes even a high "normal" for cells in the cerebro-spinal fluid is misleading. On the whole, however, the information given is accurate and well set out, and the book can be commended to students, practitioners, and laboratory workers who wish to know the full scope of laboratory diagnostic measures at the present time.

The Hair.

By W. J. O'DONOVAN, O.B.E., M.D., M.R.C.P., Physician to the Skin Department and Lecturer on Dermatology at the London Hospital; Lecturer at the London School of Dermatology, St. John's Hospital. London: J. and A. Churchill. 1930. Pp. 218. 12*s*. 6*d*.

IN the preface to this book on trichology Dr. O'Donovan mentions the neglect which the subject has suffered at the hands of the medical profession, with the consequent rapid increase of unqualified persons who claim to give expert advice on it. His aim has been to present the current teaching of dermatologists with regard to the hair. Beginning with the arrangement and pigmentation of the hair, he passes on to discuss ectodermal defects, the development and replacement of fœtal hair, and the abnormalities of development which may arise at various stages. The fifth chapter is devoted to alopecia due to scarring, and the sixth to seborrhœa of the scalp with its complications and treatment; syphilitic alopecia is discussed at length in a separate

chapter, with a reference to possible mistakes in diagnosis. In a section on the public health aspect Dr. O'Donovan gives a list of simple rules for the hairdresser attending institutions which would, if followed, prevent the spread of infective conditions; he also quotes the regulations and recommendations for the conduct of hairdresser's saloons issued by the Corporation of London. The composition of hair dyes in general use is given, and the treatment of parasites of the scalp described; the eleventh chapter deals with trichorrhexis nodosa, and the next five chapters with various types of alopecia, including those produced experimentally by thallium, inoculation, and light treatment. Ringworm of the scalp, hypertrichosis, and pseudo-alopecia form the subjects of the last three chapters of the book. The illustrations are clear and well chosen.

Practical Prevenception.

By WILLIAM J. ROBINSON, Ph.D., M.D. Hoboken: American Biological Society. 1930. Pp. 170.

THIS book is written for the medical profession only, and is especially adapted for American readers. The author is well known as a publicist, and as one of the first to advocate that medical men should interest themselves in the practical aspects of birth control. His influence in shaping American thought on this question has been felt for many years, and this book is the fruit of his long practical experience. Unlike most workers in contraception, Dr. Robinson believes very little in the efficiency of occlusive pessaries. He considers that the most efficacious method is a jelly containing a spermaticide. "It makes little difference what antiseptic or acid is used in the jelly. . . . In my opinion, a jelly containing boric acid, chinosol, and lactic acid is the best." Prescriptions are given for different jellies and suppositories which should prove useful to those medical men who have not facilities for obtaining patented articles, or whose patients cannot afford to buy them. It is contrary to American law to send contraceptives by post. In the opinion of most observers, the value of a properly fitting pessary is greater than is conceded by Dr. Robinson. It would also seem that the violence of his condemnation of the Gräfenberg ring is hardly justified by the knowledge that is as yet available of this method. The Gräfenberg ring is still in the experimental stage, and may be shown to have a value in carefully selected cases.

Diagnostic et thérapeutique électro-radiologiques

des maladies du système nerveux.

By A. ZIMMERN, Professeur agrégé à la Faculté de Médecine de Paris; Directeur de l'Institut municipal d'Electro-Radiologie; and J.-A. CHAVANY, Chef de Clinique à la Faculté de Médecine de Paris, Médecin de l'Institut municipal d'Electro-Radiologie. Paris: Masson et Cie. 1930. Pp. 654. Fr.120.

WRITTEN primarily for the neurologist, Prof. Zimmern and Dr. Chavany have compiled an interesting book, the chief feature of which is the necessary collaboration between radiographer and electrotherapist in the diagnosis and treatment of diseases of the nervous system. The book is divided into four parts, the first dealing with electrodiagnosis in all its aspects. The second, devoted to radiographic diagnosis, is well illustrated and enters fully into the technique of the injection of gas into the peritoneum, and of the subarachnoid and epidural injection of lipiodol. The third part describes various methods of treatment, and in the fourth and far the longest portion the authors discuss in detail all the diseases of the nervous system, taking, in turn, their clinical aspect, electrodiagnosis, and choice of treatment. This portion is again fully illustrated by radiograms, some of which might have been dispensed with, and their place given to illustrations of the technique of the different treatments described. The authors make no extravagant claims for the various methods, but give a well-balanced and impartial consideration to each in turn.

Indian Journal of Medical Research.

THIS issue (Vol. XVIII., No. 1, July, 1930) contains 35 separate papers on very various subjects.—J. A. Sinton reports on various species of the genus Phlebotomus, including the female of *P. nicnic* Banks, 1919, and some new specimens from Africa.—A field method for estimating salinity of water in mosquito-breeding places is also described in conjunction with N. D. Kehar.—R. B. Lloyd and L. E. Napier record a series of interesting observations on the blood-meal of sandflies investigated by means of precipitin antisera. *P. argentipes* and *P. papatasii* fed almost exclusively on the blood of cattle and man, but when both were available the blood of cattle was preferred. Their observations provide little evidence in favour of the theory of kala-azar transmission by sandflies.—J. Taylor, S. D. S. Greval, and U. Thant consider the incidence of bacteriophage in bacillary dysentery and cholera and the effects of treatment with therapeutic phage. A parallel control series was used throughout. They conclude that bacteriophage is neither essential to recovery nor an effective therapeutic measure.—T. B. Menon discusses the intestinal findings in 800 autopsies in Madras; 60 per cent. showed chronic colitis or chronic diarrhœa, the lesions strongly resembling those of chronic dysentery.—L. Dunbar and E. D. Stephens have made an analysis of the types of dysentery of the Madras district. Bacillary outnumbers amœbic dysentery by about 5 to 1, while the commonest causal organism proved a bacillus of Flexner type.—L. Wills and S. N. Talpade continue their report on the pernicious anæmia of pregnancy. They suggest that relative deficiency in vitamins A and C, or some factor associated with this deficiency is of ætiological significance, and think the proportion of fat and vitamin B in the diet may play some part in determining the incidence of this disease in populations generally short of vitamins A and C.—B. M. Das Gupta writes on the differentiation of *Leishmania tropica* from the parasite of dermal leishmanoid; the former grew more rapidly, but true lateral outgrowths were not seen.—T. A. Hughes and K. S. Malik studied the glucose and lævulose-tolerance curves in hospital patients suffering from various diseases, excluding diabetes and other endocrine disturbances. The curves proved abnormal in almost all cases, the blood-sugar being high (i.e., above 120 mg. per cent.) in 52 out of 78 cases.—A microchemical method of detecting urease within tissue is described by P. N. Sen, while K. R. K. Iyengar and W. A. Beer record Part I. of their studies on the value of etherised sheep vaccine in the treatment of rabies.—Other papers include one on the pharmacological action of opium and narcotine in malaria by R. N. Chopra and R. Knowles, and one on the action of opium in diabetes by R. N. Chopra and J. P. Bose.—N. D. Kehar records the behaviour of cinchona alkaloids towards living cells.—The distribution of lathyrism in the United Provinces is dealt with by H. Scott, as well as feeding experiments on tonga ponies with botanically pure cultures of *Lathyrus sativus* and *Vicia sativa*.

THE LANCET.

LONDON: SATURDAY, DECEMBER 20, 1930.

THE EXPERIMENTAL INVESTIGATION OF CANCER.

THE ninth scientific report[1] of the Imperial Cancer Research Fund which has just been published contains 12 original contributions and four reprints. The fact that these papers have been collected in this form is an indication that special importance is attached to them. They certainly represent noteworthy contributions to the literature of cancer. For the first time papers dealing with the filtrable tumours of the fowl are included in this series of scientific reports, the attitude adopted by cancer researchers towards this type of malignant new growth having changed in recent years. The fact that these tumours can be transmitted by cell-free material, while the transmission of mammalian tumours has never been accomplished by material free from living cells, led many investigators to doubt the true neoplastic nature of the filtrable fowl tumours. Others regarded them as atypical manifestations of malignancy, the investigation of which had little bearing on the real problems of cancer. The work of GYE was the first attempt to formulate a conception in which the development of malignancy in the filtrable fowl tumours presented merely an exaggeration of the process underlying the development of malignancy in mammals. Although the experimental evidence which he brought forward in support of his views has not been accepted, his work has had the effect of establishing the fowl tumours as true malignant new growths. The fact that filtrable tumours exhibit greater variations among themselves than was at one time realised is becoming clear. In this report Dr. J. A. MURRAY, the director of the Fund, and Dr. A. M. BEGG give accounts of two types hitherto undescribed, an endothelioma and a fibrosarcoma. It is known that filtrable tumours of the fowl are transmitted by cell-free filtrates or by dried material, and there is a rapid transformation of the normal cells of the injected fowl into malignant cells—that is to say, in the injected fowl the tumour arises de novo. A detailed study of the early stages in the development of the endothelioma showed that the endothelial cells of the capillaries at the site of the injection undergo a transformation into malignant cells. This process is illustrated by numerous drawings and microphotographs, so that the actual sequence of events can be visualised. The fibrosarcoma described is also of interest, because this neoplasm seemed to undergo a change in its biological properties in the course of its propagation. It is an exceptionally slowly growing tumour, which was at first so hard that it could not be minced for the purpose of making an extract. After several transplantations by living cells it became softer and more cellular; when an extract was made and injected the same type of tumour was produced.

The view is gradually gaining ground that the key to the cancer problem may be found in the investigation of these tumours and of the difference in their biological behaviour from that of mammalian tumours. Dr. W. CRAMER contributes two papers on this question. He points out that all the filtrable fowl tumours hitherto studied are of mesoblastic origin, and that when their transmission is effected by the injection of cell-free material a connective tissue reaction is involved. A similar transmission of an epithelial tumour to be successful obviously demands more restricted conditions. Thus a carcinoma of the ovary could only be transmitted without the intervention of living cells, if the cell-free material was actually injected into the ovary. Since most attempts to transmit mammalian tumours with cell-free material have been carried out with *subcutaneous* injections of extracts of *epithelial* tumours the negative results obtained are not conclusive evidence against the existence of an agent. Only experiments with sarcomata could yield such evidence. Extracts of mouse and rat sarcomata have given negative results, but Dr. CRAMER points out that even the Rous tumours pass through a phase when they cannot be transmitted by extracts, indicating a temporary attenuation of the agent or virus, which is further emphasised by the unavoidable loss resulting from extraction and filtration. In order to exclude this possible fallacy, Dr. CRAMER has studied the transmission of transplantable mouse and rat tumours, the cells of which had been killed by a process of repeated freezing and thawing. He found that all carcinomata treated in this way gave uniformly negative results on inoculation, as was to be expected, while the inoculation of frozen and thawed sarcomata yielded a considerable number of new tumours. The possibility that these positive results may have been due to the survival of a few exceptionally resistant cells is discussed. Experiments with tissue cultures gave no evidence of the survival of cells after repeated freezing and thawing. Moreover, the transmissibility of frozen and thawed sarcoma material is more readily attenuated by incubation or even by washing with saline than would be expected if it depended on living cells. Although this possibility cannot be excluded, the experiments show that the dogma of the non-transmissibility of mammalian neoplasms without the intervention of living cells does not rest on as secure a basis as has hitherto been generally believed.

Another aspect of the ætiology of cancer is dealt with by Mr. H. G. CRABTREE, who has studied the carbohydrate metabolism of tumours by Warburg's manometric method. He finds that different tumours exhibit wide variations in their

[1] Ninth Scientific Report of the Imperial Cancer Research Fund. 39 plates. 1930. London: Taylor and Francis. 21s.

carbohydrate metabolism. One feature, however, is common to all—namely, the power to split glucose into lactic acid even when oxygen is present. The significance of this property will be understood if it is realised that this reaction does not require the intervention of oxygen and is exhibited by normal tissues only under anaerobic conditions, and then only to a limited extent. This property of aerobic glycolysis is not specific for malignant cells, as was at one time suggested by WARBURG, but is possessed by other pathological overgrowths, such as the cellular proliferations induced by viruses. Future observations on such non-malignant pathological overgrowths will have to be carried out before generalisations on the carbohydrate metabolism of malignant cells can be made. The theory which attributes malignant changes to an alteration in the nuclear constitution of the cell is dealt with by Dr. R. J. LUDFORD. This view was held by BOVERI, who developed this idea in a small pamphlet first issued in 1914 and republished after his death in an English translation in 1929 under the title "The Origin of Tumours." BOVERI'S view was that the cancer cell owed its peculiar properties to a defect in the chromosome constitution. Recent research has, indeed, shown that the cells of malignant new growths frequently show abnormal mitoses, including mitoses with an abnormal number of chromosomes, and Dr. LUDFORD supplies a number of striking examples of such abnormalities. But it is by no means clear whether these are the cause or the effect of the malignant proliferation. A further development of BOVERI'S view has been the suggestion, first made by BAUER in 1928, that an alteration in the genes rather than the chromosomes was responsible for the malignant change—that the cancer cell was in fact a mutation of the normal cell. In a most interesting article Dr. LUDFORD gives a full bibliography of the literature and reviews the whole subject, pointing out that perhaps the strongest objection to this view is the difficulty of explaining the filtrable tumours of the fowl on such a basis. In another contribution, beautifully illustrated, Dr. LUDFORD shows how a careful study of transplanted tumours, spontaneous tumours, and tar tumours has led him to the conclusion that, contrary to the view of ITCHIKAWA and of OERTEL, "malignant growths are devoid of any specific nervous organisation." The report contains also a number of papers by Dr. L. FOULDS, who describes a rare type of tumour in the mouse—an angio-endothelioma—and deals with certain aspects of the problem of immunity to transplanted tumours, which have a bearing on the attempts recently made to apply this phenomenon of immunity to the therapy of cancer. Dr. MURRAY and Dr. CRAMER each contribute a paper on the experimental carcinogenesis by tar.

This ninth scientific report is a production worthy of its predecessors, and gives fresh evidence of the wide interests and unprejudiced attitude of the workers of the Imperial Cancer Research Fund.

A FURTHER TEST OF THE SPAHLINGER VACCINE.

Sir FREDERICK MAURICE has sent us copies of documents communicated to representatives of the daily press at the Ritz Hotel, London, on Dec. 9th. A committee of which he is a member has been controlling a test for the immunisation of cattle against tuberculosis, and feels that the moment has arrived when the results of this test should be made known to the world. The medical signatories to the manifesto include Dr. T. DRUMMOND SHIELS, Under-Secretary for the Colonies, Sir BRUCE BRUCE PORTER, Sir THOMAS WATTS, and Dr. J. H. WILLIAMS, M.P. Their report begins with a recital of experimental work carried out at the laboratories and farm of Mr. HENRY SPAHLINGER at Carouge, near Geneva, of which a preliminary account was given on pp. 107–8 of "A Book of Facts," by Mr. R. G. LOVELL (1926). Then comes the protocol of a further test made in this country. Last December, we are told, 18 calves of various breeds at a Norfolk farm were vaccinated with a single dose of a simplified bovine vaccine provided by Mr. HENRY SPAHLINGER, and said to be prepared from dead germs although not more nearly described. The injections varied in quantity from a mere trace to large doses. In July, that is six months later, all the vaccinated calves were injected with massive doses of living bovine tubercle bacilli, and all except one of the calves were alive and in good health on Nov. 23rd, that is, 19 weeks later. The calf which died on Nov. 7th had received the smallest dose of vaccine, no more than 0·05 c.cm. Four other calves injected in July with the same massive doses of living bovine tubercle bacilli, but not previously vaccinated, all died within eight weeks, the cause of death in each case being certified as tuberculosis by independent bacteriologists to whom organs were sent. These facts are regarded by the committee of control, which included two veterinary surgeons, as proof that the Spahlinger simplified bovine vaccine confers on calves an extremely strong resistance against tuberculosis, even when the virus is administered intravenously in such massive doses as to kill unvaccinated calves in about a month. The AGA KHAN, however, in an address to the press representatives, went much further than this, and stated that the vaccine solved the problem of ensuring a world supply of tubercle-free milk and meat.

The claim to have immunised cattle against experimental infection is not new. EMIL V. BEHRING made such a claim in 1902 for his bovo-vaccine, and the same claim has since been made for B C G. Both raised great hopes which have not yet been realised outside the laboratory, if we are to take the evidence of those who have tried them on the farmstead. Speaking at the recent International Veterinary Congress held in London Dr. E. A. WATSON, chief pathologist to the Animal Diseases Research Institute at Quebec, said that a comparative study in Canada over 5–6 years did not substantiate claims for B C G vaccination

as an efficient means of protection against bovine tuberculosis. His colleagues in the United States, he believed, felt the same. At the same congress came a warning from Prof. ALB. ASCOLI, of Milan, that a large number of post-mortem findings of old animals were necessary before results of inoculation from birth onwards could be ascertained. And Dr. GUÉRIN himself said it was a mistake to think that active vaccination against tuberculosis was sufficient of itself to ensure protection against the disease. It must be combined with rigid isolation immediately after birth. The congress indeed made it clear that no one has yet succeeded by vaccination in establishing permanent immunity to accidental infection from tuberculous cattle in the same shed. He who can do this will deserve well of mankind. It is true that in the recent Norfolk test with the Spahlinger vaccine the calves were housed and kept under ordinary farming conditions, and were fed on milk from cows who reacted to tuberculosis, in order to reproduce the unfavourable conditions met with in practical farming. But the test is incomplete and will remain incomplete until the life-history of the vaccinated calves is fully known.

It is in fact too early for any deduction that by systematic vaccination of this kind bovine tuberculosis can be wiped out without slaughtering diseased cattle. The group for whom Sir FREDERICK MAURICE and the AGA KHAN speak does not contain immunologists or bacteriologists whose opinion on such a vital problem would be required before the scientific world is satisfied. The Medical Research Council, or indeed any other expert body, would no doubt be willing to submit Mr. SPAHLINGER'S vaccine to a searching test. There is prima facie ground for doing so. If the vaccine were to be placed on the open market it would be possible for others to repeat and confirm the Norfolk test. But if the test is now used as the basis for an appeal to provide funds, the truth may be hard to come at.

THE TERCENTENARY OF QUININE.

IT has been said that the discovery of quinine established colonies and changed the face of history. The tercentenary of this great event has been fitly celebrated during the past two weeks by a special exhibition and series of receptions at the Wellcome Historical Medical Museum. The exhibits include specimens culled from many sources and many periods; photographs, paintings, engravings, manuscripts, and books—everything, in fact, that could conceivably interest or instruct the seeker after knowledge concerning malaria or quinine. Among the most striking were three of the original serons of cinchona bark brought from Peru by RUIZ and PAVON to CARLOS III, in 1777; these, together with specimens of Loxa and Calisaya bark, had been presented by the KING of SPAIN, and showed the old mule boxes in their original rawhide coverings, just as they came down the mountains of Peru 250 years ago. The receptions were made an occasion for illustrating the cosmopolitan circle which quinine unites in its interest. A dozen nations sent representatives to do it honour; one nation discovered it, another published its secret, a third popularised it, a fourth grows it, a fifth purchases it.

Quinine is a world's possession and must be grown by the nation which happens to possess both soil and climate suited to its whims, for it is no hardy universal, as Sir DAVID PRAIN pointed out, but a real problem to the cultivator. By what he described as an "accidental preference" the alkaloid quinine became officinal and remained the only one so honoured. Being therefore the one most frequently prescribed, it is the one most in demand, and the planter must plant accordingly, for the manufacturer pays for his cinchona bark in terms of its quinine content. Java has no cinchona monopoly, but its soil and climate have given it a quinine monopoly because the yellow bark, which happens to be richer in this alkaloid than any other, will only flourish in Java and Bolivia. While quinine remains the alkaloid of official and popular choice it is unlikely that the others will be produced on a large enough scale to show whether they are equally effective in preventing and controlling malaria; but it is a point which should be determined, for other kinds of bark yield other alkaloids more richly and at the same time adapt themselves better to other climatic conditions. In any sample of "crown" bark, whatever its total alkaloid content, some three-fifths to three-quarters will probably be quinine; in "red" bark not more than one-quarter will be quinine; while in a good "yellow" bark four-fifths will be the officinal alkaloid, and in "grey" bark there will be but traces of it. Mr. A. R. MELHUISH deplored the small proportion of the world's cinchona that comes from within the British Empire; the answer lies not with increased enterprise on the part of the cultivator, who is helpless so long as quinine is demanded, but with the medical profession, who can tell him whether or not it is any use cultivating a kind of bark poor in that particular alkaloid which has hitherto held the world's market.

MERSEYSIDE HOSPITALS BUDGET.—The voluntary hospitals represented on the Merseyside Hospitals Council have just prepared their budgets for next year. The estimated total ordinary income, apart from legacies and unforeseen gifts, is £189,467, and the estimated ordinary expenditure £339,875. Towards the deficit of £150,408 the Merseyside Hospitals Council will be able to allocate £103,500 from the penny-in-the-pound scheme, leaving nearly £47,000 to be provided by new money, the source of which is at present not obvious. Meanwhile, the Royal Southern Hospital has been obliged to sell all its available securities, amounting to £13,000, to reduce its debt of nearly £41,000. Several hospitals are contemplating special expenditure not included in the budget figures. The most important of these estimates are: Royal Southern Hospital, £17,000 on new X ray department and extension of operating theatre; David Lewis Northern Hospital, £25,000 on new out-patients' department, &c.; Liverpool Radium Institute, £20,000 for completion of new building; St. Paul's Eye Hospital, £25,000 for new out-patients' department; Birkenhead General Hospital, £12,000 on nurses' home extension and X ray department extension; Samaritan Hospital and Hospital for Women, £24,000 towards the building of the new hospital.

ANNOTATIONS

BIOLOGICAL EFFECTS OF X RAYS.

In a noteworthy contribution Prof. Sidney Russ and his co-workers record the results of experiments, carried out at the Middlesex Hospital[1] over a period of three years upon the cat and the rabbit. X rays of two different groups of wave-length were used corresponding to voltages of 150,000 and 230,000 respectively. The minimum dose of radiation necessary to produce the death of the animal was determined for each type of radiation, the whole animal being exposed. It was found that the minimum lethal dose of the more penetrating radiation was less than that of the other type in the ratio of 1 to 2·8. The tissue changes produced were most marked in small intestine, stomach, liver, spleen, respiratory tract, and white blood cells, although destructive changes could be produced in any tissue by the administration of sufficiently large doses of radiation. In the small intestine there was widespread destruction of epithelium with petechial and even larger hæmorrhages; infection occurring at a later stage appeared to be secondary to the destructive effects. Similar changes were found in the stomach. The large intestine was more resistant. In the liver, congestion and fatty infiltration were produced, with patches of necrosis. In the lungs changes were found in the epithelium of the trachea and larger bronchi, with patchy areas of hæmorrhagic and œdematous infiltration of the alveoli; at later stages endothelial proliferation was observed in the alveolar walls and areas of fibrosis. When, however, the lungs alone were irradiated they were found to be resistant to radiation, the changes described being due in the authors' view to the occurrence of infection. In the blood the effects were marked diminution in the lymphocyte content, followed later by diminution of the polymorphonuclear cells; indeed, in some of the experiments the leucocytes almost disappeared from the blood for a time. Little or no effect was observed on the platelets.

In some of the experiments localised regions only were exposed, and it was found that the typical changes in the abdominal organs were only produced when these were directly irradiated. Bacteria were frequently found in the blood at a late stage. In the authors' opinion infection plays an important rôle in the production of tissue changes, entering the blood stream, it is believed, through the damaged intestinal wall. They refer to work of Cramer, Drew, and Mottram, in which the entrance of bacteria into the circulation was ascribed to thrombopenia produced by the rays—an effect not observed in the present experiments. But Cramer and his colleagues later inclined to the view that the thrombopenia was secondary, and that infection arose from the damaging effect upon the tissues. After large doses of radiation a state of cachexia was produced in the animals somewhat resembling the clinical condition known as "X ray sickness." In view of the fact that histamine or a similar substance is known to be liberated by tissues damaged by X rays, experiments were undertaken to determine if the absorption of such a substance might be responsible for the production of this condition. It was found that the effects of histamine injections did not bear any great similarity to X ray cachexia. An interesting feature of the research from the clinical point of view was the investigation of the effects of liver feeding on the development of the X ray anæmia. Little or no influence upon the anæmia was detected, but in the animals to which liver had been administered there was an apparent increase in the sensitivity of the liver itself to the radiations. In all these animals more extensive destructive changes were observed in the liver as a result of the irradiation than in non-liver-fed animals with similar doses. This observation should lead to caution in the administration of liver extract in the hope of benefiting the anæmia produced by clinical irradiation.

The authors point out that inferences drawn from the results of experiments on lower animals may or may not be applicable to the human subject, and it is to be noted that the doses of radiation which they employed were relatively much greater than those applied in clinical work. Certain of the results however, have their clinical implications. Most important, perhaps, is the occurrence of septicæmia after irradiation of the abdomen, more particularly in view of the fact that mild intestinal lesions are not infrequently produced clinically in the treatment of malignant disease in the abdomen with heavy doses of radiation. Moreover, the fibrosis of the lungs which they describe agrees with the well-known clinical observations of Finzi and of Wintz; if, as the authors believe, this condition is due to infection attempts might be made to combat it on appropriate lines. Another observation which may prove to be of possible clinical importance is the fact that recovery may appear in the leucocyte count after almost complete disappearance of leucocytes from the blood. Nothing is known at present clinically as to the point at which an X ray leucopenia becomes dangerous. Finally, the authors suggest that further study might be undertaken of the effects of different diets during X ray treatment in relation to the occurrence of X ray sickness. Certain differences in the general effects between the cat and the rabbit might be due to the widely differing diets of these animals.

[1] The Physiological and Cytological Effects of Penetrating X Rays upon the Cat and the Rabbit. By S. Russ, Samson Wright, H. A. Bulman, and L. H. Clark. Reprint from Proceedings of the Royal Society of Medicine, Section of Electro-Therapeutics, Oct., 1930, pp. 43–60.

ROAD ACCIDENTS IN DENMARK.

One of the measures which is assuredly calculated in the long run to check the rising incidence of road accidents is an international pooling of experience—a comparison of the various means adopted in the different countries to reduce this evil to a minimum. It was, therefore, a most opportune study which Dr. F. Svendsen, of the Danish Red Cross Society, presented in October to the fourteenth International Red Cross Conference held in Brussels. After briefly reviewing the statistics for the United States and showing that the deaths from road accidents in 1929 in this country were nine times more numerous than those in 1911, Dr. Svendsen gave the following statistics for Denmark for the first six months of 1930.

	Motor accidents.	Other road accidents.	Total.
Number	4450 ..	855 ..	5305
Killed	96 ..	15 ..	111
Injured	1903 ..	641 ..	2544
Badly injured ..	977 ..	332 ..	1309

It should be noted that these figures deal only with accidents brought to the attention of the police, and

do not include any of which the police took no cognisance. More than half of all the accidents—i.e. 2727, occurred in Copenhagen, with a population of 708,600. The total population of Denmark is 3,518,000. As great a proportion of the accidents as 83·9 per cent. concerned motor-cars. In 55 per cent. of the traffic accidents, the blame was laid exclusively on the drivers of motor-cars; in 13·7 per cent. bicyclists were held responsible, in 8·5 per cent. pedestrians and passengers; only in 2 per cent. were physical conditions, such as the state of the roads or visibility, held responsible, and in 1·2 per cent. the state of the motor vehicle. In the remainder, the responsibility was shared by a combination of two or more of the above factors. Travellers familiar with the swarms of bicyclists in the streets of Copenhagen will not be surprised to learn that they and pedestrians play a much more important part in the genesis of motor accidents than is the case in other countries. Among the improvements effected of late, the filling in of ditches beside the roads in order to provide bicycling paths deserves special mention. This reform has been made possible by the arrangement which allots part of the revenue from motor-car taxation to the local authorities. There are over 2500 doctors in Denmark—i.e., one for every 1360 inhabitants, and if Copenhagen and its 629 doctors are discounted, the proportion of doctors to inhabitants is as one to 1500. Thanks to the comparative density of the population even in the country, the radius of action of a general hospital (of which there were 170 in 1929) is seldom more than 15 kilometres. Copenhagen is served with 16 and the rest of the country with 139 ambulances, the radius of whose action is about 15 kilometres. For the purpose of comparison it should be noted that the corresponding radius of action in England is about 25 kilometres. The part played by the Danish Red Cross with regard to ambulances consists largely of financing them at the outset; later, they are often taken over and run by the local authorities.

AVERTIN IN OPHTHALMOLOGY.

IN the *British Journal of Ophthalmology* for November Mr. O. Gayer Morgan and Mr. J. M. Lees record their experience of rectal narcosis with avertin, based on more than 50 cases, including cataract extraction, acute glaucoma, excision, evisceration, acute dacryocystitis, removal of the lacrymal sac in chronic dacryocystitis, and minor and major plastic operations on the eyelids. They conclude that it is not a dangerous drug when given with care, and that it well merits a trial in ophthalmic surgery. The amount injected should never exceed 1·0 g. per kg. of body-weight, and the temperature should not be more than 40° C., for otherwise the avertin may decompose and set up colitis; to ensure against this two drops of Congo red solution can be added to 5 c.cm. of avertin, and decomposition will be shown by appearance of a blue colour. If any of the solution, as injected, be returned by the patient it is unsafe to attempt to make up the amount by an extra injection, since absorption is so rapid that it is impossible to estimate how much of the drug has been rejected. In most cases no other anæsthetic, general or local, was used, but Morgan and Lees employed a preliminary injection of morphia gr. ¼ with atropine gr. 1/100, though this is not considered necessary. If the claims of its advocates are confirmed the drug has obvious advantages where a general anæsthetic is contra-indicated or a local anæsthetic is insufficient. In cataract extraction it is chiefly applicable to very nervous patients who cannot be relied upon to keep still during the operation, but when operating with avertin it is necessary to fix the eyeball firmly with forceps during the incision, and this fixture is not so convenient as voluntary depression by the patient himself in obedience to the surgeon's directions. Nevertheless any method of relieving apprehension either before or during an operation on the eye is worth a great deal. The main contra-indications to the use of avertin are a serious degree of nephritis or severe disturbances of the liver. Old age is not itself of importance, and though the authors of this paper have not used the drug on children under 16, there seems to be no reason why they should not do so. Avertin is a narcotic rather than an anæsthetic, and one of its main advantages is that it can be used to remove the patient's anxiety for an hour or so before operation.

THE I.M.S.

IN an ample quarto volume Lieut.-Colonel D. G. Crawford, whose "History of the I.M.S." did very nearly as much for the service as Boswell did for Dr. Johnson, has continued his labours in a volume entitled "The Roll of the Indian Medical Service."[1] The title is, perhaps, unfortunate, since it suggests a book on the lines of the Army List or Bradshaw. In fact Colonel Crawford takes the opportunity, in the introduction, of bringing his history up to date, and apart from the brief individual records of service many notes testify to the enterprise of the author in discovering interesting material in the most unexpected sources. The term I.M.S. has been used in a very broad sense to cover the name of every man who served, even for the shortest period, in the East India Company's land medical services, including the surgeons' mates (assistant surgeons), who were not commissioned officers, but served under warrants issued by the colonels commanding their regiments. Some remarkable histories may be deduced from the laconic entries in this Roll. In the Madras list occurs the name of Mungo Park, the son of the famous African explorer, who had himself been surgeon's mate of an Indiaman. Readers of Lockhart's "Life of Scott" may remember how the father, having obtained by influence the promise of a post in the company's service, provided he could qualify as a surgeon, rushed off to commence his medical studies, and in six months time returned with the required diploma. Other even more striking examples of adaptability are not difficult to find. A sergeant in the St. Helena garrison was given dispensary duties, and having served in that capacity for 15 years was appointed assistant surgeon. Later he went to England, obtained the M.R.C.S., and returned eventually to become full surgeon at St. Helena. As time went on, and medicine rose in the social scale, I.M.S. men not only cured the wives and families of potentates, and shook pagoda trees, but distinguished themselves in many other ways, rendering eminent services in several branches of science, furnishing distinguished administrators and diplomats, and founding commercial houses the names of which are still household words in India. The firm of Jardine and Mathieson was started by one of the company's surgeons, and the well-known publishing house of Thacker and Co., which produces Colonel Crawford's work, is also said to have had a medical origin.

The Roll contains several interesting appendices, notably tables of honours and rewards, and analyses of

[1] Roll of the Indian Medical Service, 1615–1930. Compiled by Lieut-Col. D. G. Crawford, Bengal Medical Service, ret. London: W. Thacker and Co. 1930. Pp. 711. 28s.

degrees and diplomas and medical schools. As regards academic distinctions, the service has always been well to the fore; a large proportion of officers have held one or more of the higher qualifications, many of them acquired in middle age after special courses of study. A curious feature is the apparent unpopularity not only of the I.M.S., but the R.A.M.C. and Naval Medical Service, with the northern English schools. Some names from these schools are no doubt entered under the other universities or the London medical schools, but there is an almost entire absence of entries under Liverpool, Birmingham, and Leeds degrees in the various lists, and only a moderate representation of Manchester. The Scotch and Irish universities, on the other hand, have always been well represented, as also the London schools, and there are a fair number of men with the London and Cambridge degrees. The inscription on the title-page of this book is somewhat sinister, yet Colonel Crawford had words of modified cheer for the service when he presided at the annual dinner two years ago. He said that though they could no longer hope to obtain diplomatic plums and provincial governorships, many attractive openings remained, and plenty of opportunities for useful work. The old Indian service families still send their sons into mercantile firms in India, if not so many as formerly into the services themselves. It is justifiable to hope that the I.M.S. in a contracted form will take on a new lease of life under the changed conditions which the next few years will see.

HYPOGLYCÆMIA FOLLOWING INSULIN TREATMENT.

THE fear of hypoglycæmia should no longer deter patients from using insulin for diabetes. The symptoms of overdosage can readily be recognised; and there is a simple and satisfactory remedy in the administration of glucose by the mouth, by rectum, or, if necessary, by intravenous injection. Although slight symptoms are common—indeed, some experienced physicians allow their patients to become a little hypoglycæmic in the early stages of treatment so that they may learn the sensations and how to combat them—actual coma from insulin hypoglycæmia is rare. Deaths have, of course, been reported, but in fatal cases there have usually been additional complications, such as extreme inanition, Graves's disease, pancreatitis, acute alcoholism, or gross carelessness. F. Rathery and Sigwald [1] point out, however, that nowadays insulin is widely used in the treatment for conditions other than diabetes and here the risk of hypoglycæmia is certainly greater, since the blood-sugar is not above normal to begin with. They report a fatality following insulin treatment combined with glucose administration, the patient being a young woman under treatment at a sanatorium for Pott's disease of the spine. Because of failure to gain weight, loss of appetite, vomiting, and signs of acidosis, insulin had been given together with intravenous and rectal injections of glucose. When seen by Rathery and Sigwald she was in deep coma, breathing five times per minute though not cyanosed, with tetany of the hands and exaggeration of tendon reflexes. The blood-sugar was reduced to 20 mg. per 100 c.cm. In spite of treatment and raising the blood-sugar to 149 mg. per 100 c.cm. the coma deepened and the patient died. At autopsy there were bilateral pleural adhesions with consolidation at the left base, old tubercle at the right apex, but no signs of meningitis or other alteration sufficient to explain the coma. It was concluded, therefore, that death was due to coma resulting from the administration of insulin, of which 260 units had been given in six days.

WHO WAS WHO.

To the November issue of the *King's College Hospital Gazette* Mr. Willoughby Lyle contributes an article which will be found extremely useful to many readers. It is a summary of the history of the medical school, composed mainly of biographical details of the medical staff up to 1913. During the centenary of its existence the hospital and school have enjoyed the assistance of a remarkably brilliant staff, a large proportion of whom received their preliminary education at the College. The reason why the article is so particularly valuable is that in each case the year of the appointment of these men is clearly stated, as well as the length of their tenure of office, so that it is easy to see which of them functioned simultaneously at King's, and who were their analogues at other medical centres. The biographical notes are supplemented by interesting details in the domestic history of the College. We are thus introduced to such an episode as the discovery of Carlo Ferrari, the murdered Italian boy, in the prosector's room, while characteristic sayings of such well-known heroes of the past as George Johnson, Richard Partridge, William Fergusson, and John Curnow are recalled to memory. A certain number of the staff of THE LANCET of 40 years ago will remember their brilliant and erratic colleague, Curnow, whose success as student, demonstrator, and teacher, was so entirely out of proportion with any position to which he ever attained as practitioner. It would be extremely useful for the purposes of many medical writers if the editors of all the hospital gazettes would publish a similar article concerning their own great men, for over and over again in medical writing—in text-books as well as in essays and journalistic work—it may be necessary, for the clinching of an argument or the provision of an illustration, to allude to some particular work or occurrence associated with a name, when dates and the identifications of institutions and contemporary workers become significant.

PATHOLOGY OF CARDIOVASCULAR SYPHILIS.

IN 1914 A. S. Warthin reported a very high incidence of syphilis in post-mortem material; he stated that the characteristic lesion of syphilitic infection of the heart is a localised interstitial myocarditis, and claimed to have demonstrated spirochætes in these lesions. In the Lumleian lectures this year Carey Coombs [1] said that he has been unable to confirm these findings. As he sees it, cardiovascular syphilis is essentially a lesion of the root of the aorta, the heart being affected in two ways as a result of this aortitis. First, the aortic valves become incompetent with the development of aortic regurgitation, and secondly, and by far the more important, the mouths of the coronary arteries become choked by the swelling of the aorta, thus cutting off the blood-supply of the heart. Coombs finds the rest of the coronary tree, beyond the origin, to be normal except for a slight degree of associated arterio-sclerosis. In the myocardium itself he found no significant morbid lesion except hypertrophy, and this depends for its occurrence on the existence

[1] Coombs, C. F.: THE LANCET, August 2nd, 9th, and 16th, 1930.

of aortic incompetence. A symposium on cardiac syphilis in the October number of the *American Heart Journal* suggests that the majority of American workers agree with these findings and have failed to confirm Warthin's statements. Martland [2] suggests that the mediastinal glands filter the spirochætes from the circulation and act as reservoirs in which the organisms lie latent for many years. Further, he believes the earliest stage in the involvement of the aorta to be an invasion of the adventitia by spirochætes carried along the perivascular spaces around the vasa vasorum by retrograde flow from the mediastinal glands. He explains the low incidence of congenital syphilis of the heart and aorta by saying that in the fœtus the circulation in the lungs is so small that comparatively few spirochætes traverse the lungs and thus few are filtered off and stored in the mediastinal glands; therefore in congenital syphilis the aorta—which in acquired syphilis is infected from these glands—escapes.

FOCAL SEPSIS AND EYE DISEASE.

AT a meeting of the Medical Society of London, held on Dec. 8th, a discussion took place on the relation between certain diseases of the eye and inflammatory foci in other parts of the body. Mr. A. F. MacCallan grouped such diseases under three headings: (1) those which can be cured by the removal of the source of infection, including increase of lacrymation, recurrent tarsal cysts, phlyctenular conjunctivitis and keratitis, and some cases of iritis in which the focus of infection is oral or tonsillar; (2) those which can be alleviated, including other cases of iritis, irido-cyclitis and choroiditis, and also progressive myopia, an important disease, most cases of which, he maintains, have an intimate connexion with sepsis; (3) those not necessarily caused by, but associated with sepsis, a division in which he includes incipient cataract, peripheral striæ in the lens being regarded as an indication for a thorough investigation into the condition of the teeth and tonsils; glaucoma simplex, many cases of which can, he believes, be cured by non-operative measures, once the source of infection is removed; and lastly certain cases of detached retina, due to exudation from the choroid into the subretinal space, and in which no holes exist unless they are allowed to go on without removal of the focus of infection. Over and above these cases Mr. MacCallan maintains that certain cases of vitreous opacities or vitreous "dust," in which the visual acuity is not necessarily affected, can be cured by the removal of septic foci. Apart from the teeth and the tonsils such foci should be looked for in the nasal sinuses, the intestinal canal, or the prostate. Emphasis was laid on the importance of careful investigation into all these possible sources of infection before the performance of any major operation on the eye. Mr. Ernest Clarke added to the list of ocular diseases associated with sepsis several cases of retinal hæmorrhages—generally small hæmorrhages into the nerve-fibre layer—due to septic infection, and he showed several striking pictures of retinal conditions before and after appropriate treatment. Sir William Willcox added to the list of eye diseases which may be caused by sepsis by including thrombosis of the central artery of the retina and retro-ocular neuritis. Dr. Moreland McCrea, who has described [3] appearances somewhat similar to those mentioned by Mr. Clarke, under the title "retinal petechiasis," raised the question how long after the removal of a septic focus in the body is it safe to undertake a major operation. He was inclined to allow a period of six months, but Sir W. Willcox was sure that an interval of three weeks was sufficient. The question must in practice be decided in relation to the extent of the sepsis on the one hand and the urgency of the operation on the other. Although there were dissentients, the consensus of opinion at the meeting was to emphasise the importance of focal sepsis in a variety of eye diseases.

ANTENATAL SUPERVISION.

As a result of their investigation into two thousand deaths of women in childbirth, a Departmental Committee noted [1] the absence of antenatal care in 17 per cent. On this and other similar experience the Ministry of Health bases a belief that one of the essential measures for securing a reduction in maternal mortality is a general and sustained effort to enlighten the women of the country on the importance of antenatal supervision. Circular 1167, issued to maternity and child welfare authorities, mentions the decision of the Government to undertake the necessary negotiations with the authorities concerned, with a view to formulating a scheme on a national basis for the care of maternity. The additional expenditure, it is remarked, will be small in comparison with the advantages to be gained, and the development is one of the extensions in consideration of which an additional amount of £5,000,000 was included in the exchequer contribution under the Local Government Act for the next three years. Many local authorities have already provided facilities for antenatal supervision, but (Memo. 156/M.C.W.) it is not sufficient to organise clinics without associating the doctors and midwives practising in the area much more directly than has yet been done with the centre and its staff. The antenatal centre suffers from the disadvantage that the doctor in charge seldom if ever actually delivers the patient or is called in by the midwife in an emergency. For this reason closer coöperation between the centre and the doctors practising in the area which it serves is clearly desirable. In the case of women who engage a doctor for the confinement, the necessary antenatal supervision will be undertaken by him, and in the case of women who are insured persons the insurance practitioner is responsible for medical attendance during pregnancy. For these women the antenatal centre should be available for any additional care considered necessary. But there are uninsured women who engage midwives for the confinement and are not in a position to pay a doctor's fee for antenatal supervision. For these also provision is recommended through the maternity and child welfare service, and at a clinic, if accessible and the patient is willing to attend. But in sparsely populated areas it is impracticable to provide centres within a reasonable distance of the women's homes, and in towns there are many women who cannot be persuaded to attend the centres. Some county councils are already making arrangements with private medical practitioners to undertake routine antenatal examination of uninsured women who have engaged midwives for the confinement, and the Ministry looks to an extension of this arrangement also in urban areas. It is suggested that the local authority should prepare a list of doctors practising in the area who are willing to undertake this service. For the staffing of the antenatal centres it is regarded

[1] See THE LANCET, August 9th, p. 321, and August 16th, p. 367.

as preferable to secure the part-time services of private practitioners who possess the special qualifications prescribed by the regulations. Where it is possible facilities should also be provided by other doctors to see their patients at the centre if they so desire. Arrangements on these lines should prove to be one of the most helpful ways of teaching women to accept antenatal supervision as part of the normal preparation for confinement.

THE PROHIBITION OF VIVISECTION.

ON Tuesday last Commander Kenworthy asked leave to introduce a Bill into the House of Commons "to prohibit the expenditure of public money on vivisection experiments." The B.M.A. had issued a circular letter to the Members setting out the usual, and unanswerable, warnings against the dangers of such a measure. The letter explained that the word vivisection implies in the popular mind serious operations which, while they are only permitted by an Act of Parliament to be performed under efficient anæsthesia, form but a fraction of the experiments done for the routine purposes of general health, or for assisting in the medical treatment of individuals and of the community. The potency of many remedies in use to-day, notably glandular extracts, vaccines, sera, and some drugs, such as arsenicals (e.g., salvarsan) cannot be determined except by animal experiments; without being so tested they may be uselessly weak or dangerously strong. Lives depend upon these powerful medicaments being of standard strength, while the amount of diminution of pain and simplification of treatment that may result from the right employment of such a drug as pituitary extract is an unanswerable argument for the use of the products of animal research. Against the value of this drug we must balance the danger of an overdose, but by proper control the standard of potency, expressed in definite units, has been secured. The Medical Research Council is responsible for this standard, and the letter points out that the effective control of therapeutic substances can only be ensured by the State—that is to say, by the expenditure of public funds. Assuredly persons, who are really and widely humane, can only desire to arrest physiological research from a misunderstanding of what that term implies. Leave to introduce the Bill was refused by a small majority.

POST-GRADUATE COURSE IN PSYCHOLOGICAL MEDICINE.

AT the Tavistock Clinic on Dec. 17th the concluding lectures were delivered of an introductory course on psychological medicine for the general practitioner. Dr. H. Crichton-Miller, whose 12 lectures dealt with type psychology, explained, as a preliminary, that the course had come into being because the clinic was in great financial need, and that the proceeds of his lectures and those of Dr. E. Graham Howe were to be devoted to its support. The gain to the clinic will not have been only a material one. An audience of nearly 100 assembled every week at Friends House, since the class was too large to be accommodated in the house at Tavistock-square. Both courses were admirably framed, and their arrangement must have involved careful planning. The audience here, as in most groups of medical men and women who wish to be brought up to date in any subject, included doctors whose qualifications were taken very early as well as very late in the first quarter of this century. The problem of presenting psychological medicine to a class of such varied experience and training differs from that of presenting, say, biochemistry to a corresponding group. In both subjects the stage has often been shifted during the last 25 years and the old backgrounds have been replaced. The risk in designing courses on biochemistry is that a recapitulation of the changes in outlook may bore those to whom they are familiar, while the more senior devotees of litmus paper will remain for ever unconvinced of the importance of the hydrogen-ion concentration or of other conceptions now held to be fundamental. The risk involved in the presentation of modern views on psychology and psychopathology is more serious. It is that the course will be full enough to arouse but not full enough to allay that resistance which is the natural reaction to new ideas when these threaten the accepted canons of good taste. Here a gradual progress led to the smooth acceptance of unfamiliar dogma. The appreciation of the class was manifest in their punctual attendance not only at the lectures but at evening seminars held at the clinic, where questions could be freely asked and difficulties explained. If similar classes could be organised in different centres throughout the country, they should be assured of equal success.

THE SUPPLY OF HELIUM.

AT the time of the disaster to airship R101 we were informed that legislation was to be introduced in the United States to permit the exportation of helium for the use of foreign aircraft. Section 4 of the Act of 1927 prohibiting this exportation has now become inoperative, as Mr. H. B. Milner points out in an informing note on the Denationalisation of Helium in *Nature* for Dec. 13th. Mr. Milner sets out the astonishing progress made in obtaining helium in a pure condition at a moderate cost. In April, 1928, the U.S. Government began to develop the production of helium-bearing gas at Amarillo in Texas, and in August a new well at Soncy, six miles from Amarillo, was found to provide a flow of 7,000,000 cubic feet per day of a gas containing 1¾ per cent. by volume of helium. In May, 1929, the first tank car containing 200,000 cubic feet of helium was despatched to Virginia for use in U.S. army dirigibles. In September, 1929, the Texas well provided more than 850,000 cubic feet of helium of 97·7 per cent. purity, and the output for the year ended June 30th, 1930, amounted to 9,800,000 cubic feet. The price per 1000 cubic feet of helium came down from 17·63 dollars in September, 1929, to 9·64 dollars in January, 1930. An official American communication states that under present conditions it costs less to operate airships with non-inflammable helium than it would cost to operate them with flammable hydrogen. It seems then that we are within sight of the possibility of replacing hydrogen by helium in our own airship construction.

THE President and Mrs. Watts Eden will receive the guests at a reception to be held by the Royal Society of Medicine, at 1 Wimpole-street, London, from 8.30 P.M. on Jan. 21st, 1931. Dr. Arnold Chaplin will give an address entitled Great Figures in History or Misconceptions Removed.

THE Royal College of Physicians of London will be closed from Wednesday, Dec. 24th, until Wednesday, the 31st, both days inclusive.

CLINICAL INTERPRETATION OF AIDS TO DIAGNOSIS

A Series of Special Articles, contributed by invitation.

LXXXIX.

BACTERIOLOGICAL EXAMINATION OF WATER.

PART II.*

Fallacies of Occasional Examination.

BACTERIOLOGISTS are frequently asked to examine an isolated sample of water and to give an opinion on its suitability for drinking purposes. This sample may have been collected by someone having no real knowledge of water examination. These reports are given, I think frequently, but in my opinion they are usually of very little value. Standards of bacterial purity have been laid down by individuals and even by committees of bacteriologists, but the experienced water bacteriologist realises that these standards have to be used with a great deal of care, and we all agree that before attempting to give an interpretation of the results of a bacteriological examination of water it is essential to have particulars of the methods of collection, the time at which it was collected, &c. Wherever possible the bacteriologist should be given information of the gathering ground so that he is acquainted with the possible sources of pollution. To take only one example: an open reservoir near the sea-side may become contaminated by excreta from sea birds, and, if this factor is not recognised, or not known, by the bacteriologist his report may be of no practical value. He may condemn a water-supply which from a health point of view may be an excellent one.

The methods of examination are, on the whole, satisfactory, but they are necessarily purely arbitrary, and do not pay sufficient attention to the chance variation of samples. The whole aim of the examination is to find evidence of excretal pollution. With our present methods we are rarely able to isolate from the water disease-producing bacteria, such as *B. typhosus*, &c., and, therefore, we content ourselves with finding the number of living bacteria, and particularly those of intestinal origin. As I have already emphasised, the greater the number of living bacteria the greater is the amount of decomposing organic matter, and the more intestinal bacteria found the greater is the chance of there being amongst them disease-producing ones. This is only a probability and, after all, the evidence is circumstantial, and a verdict which condemns the water cannot fairly be given unless the bacteriologist has a good knowledge of his supply and has carried out several examinations.

Some Working Standards.

Household water.—In a household water-supply there is the possibility of contamination from dirty taps, &c., and, therefore, in collecting a sample, the orifice of the tap should be burned with a spirit lamp or flame of some kind, and the water allowed to run freely for at least five minutes, before the sterile vessel into which it is to be collected is filled. Again, leather washers may be a source of pollution, and the bacteriologist must be fully alive to all such sources of contamination. The best sterile receptacle is a bottle of 4 or 6 oz., boiled for five or ten minutes. This should be filled and stoppered with a cork that has also been boiled. The sample should be sent to the laboratory as soon as possible after collection. If the water is satisfactory, that is to say, if it contains no *B. coli* in 60 to 80 c.cm., the need for a second examination is hardly necessary, but if the water contains *B. coli* in 10, 20, or even 40 c.cm., then it should be regarded with suspicion; but it should not be condemned until at least two other samples confirm the finding. The organisms are not uniformly suspended in water, and it may chance that in a single sample a number of bacteria in a small piece of organic matter may have got into the specimen, and a sample taken immediately afterwards may be free.

Deep well, or spring water.—In dealing with deep well water or water from springs where there is little chance of pollution, *B. coli* should be absent in 80 to 100 c.cm., and the total bacteria count on gelatin in three days at 20° should not exceed 200 per c.cm. Grown on agar at 37° most of the ordinary water bacteria fail to develop, and therefore the total bacteria on agar should not exceed 10 to 20 per c.cm.

With *upland surface water*, such as is the supply of most large cities, and especially where filtration is effective, the total bacteria count on gelatin in three days at 20° should not exceed 400 (very commonly it is between 50 and 100), on agar at 37° 10 to 30; and the *B. coli* should be absent in 40 to 60 c.cm., in an average of three to four specimens. On one examination alone, *B. coli* in even 10 c.cm. might indicate a satisfactory water-supply.

The presence of streptococci and B. *welchii* are not common, and need not be dealt with in this article.

Conclusion.

As I have already indicated, the real object of a bacteriological examination of water in this country is to ensure a pure supply—that is, one free from the disease-producing intestinal organisms. For many years typhoid fever was the disease we wished specially to guard against. More recently the paratyphoid fevers have taken the place of typhoid. Dysentery, particularly the bacillary form, is much more common within the last few years, and some of the food poisoning organisms—e.g., Gaertner's bacillus—have been found in a water-supply. These food poisoning organisms are not uncommon in the lower animals—mice, birds, &c.—and, consequently, may get into a water-supply.

With this knowledge it seems to me that a regular and a very thorough bacteriological examination of our water-supplies is essential, but the interpretation of the results calls for special care and experience.

HOSPITAL ACCOMMODATION IN LEEDS.—Last week Lord Moynihan, by invitation, formally presented a cheque from the Leeds Jewish community for the endowment of a bed at the local Herzl-Moser Hospital in the name of Mr. Lyle Goodman, an active worker on behalf of that institution. Speaking upon the need for coördination of hospital services, Lord Moynihan alluded to the fact that while there were at the moment 1319 patients awaiting admission to Leeds General Infirmary, at the St. James's Hospital there were empty beds.

THE VALUE OF FOODSTUFFS FOR VITAMIN A.

By E. M. Hume
AND
H. Henderson Smith.

(*From the Department of Experimental Pathology, Lister Institute.*)

The discovery that purified carotene is a substance which provides a source of vitamin A of constant value when tested biologically on animals has brought the accurate standardisation of food materials for their value in vitamin A appreciably nearer. According to the differing biological techniques used, the minimum daily dose of carotene for a rat, deprived of vitamin A, has been found by some workers to be from 0·005–0·01 mg.[1] [2] and by others to be about 0·003 mg.[3] The former required a considerable growth performance from their experimental animals; the latter used as their criterion the maintenance of the depleted animal over a set experimental period. The exact particulars of the latter method are set out in the paper referred to,[3] and we have now used it for some little time. No attempt has been made to apply it methodically to the evaluation of food materials, but a few scattered observations have been obtained which are instructive in several ways. They seem to show that it would be easy to standardise food materials against carotene for their value in vitamin A, and that the minimum dose of some common foodstuffs is considerably smaller than had been supposed.

Much of the earlier work on the evaluation of foodstuffs for vitamin A was very roughly done; the materials to be tested were only fed as percentages in the diet, so that the actual daily minimum dose for an individual was not ascertained, but could be approximately worked out. A certain amount of more accurate evaluation has been done more recently, but the biological technique has always yielded results which were not very easy of interpretation. Dye, Medlock, and Crist,[4] for instance, used 0·2 g. as their smallest daily dose of green lettuce, and obtained maintenance and fair growth with it; but they did not test any smaller doses.

Till recently the minimum daily rat dose of the foodstuffs commonly deemed to be the richer sources of vitamin A were, with the exception of cod-liver oil, thought to be of about the magnitude of 100 or 200 mg. We, ourselves, used daily supplements of 200 mg. of fresh green prickly seeded spinach (*Spinacea oleracea*) or of 100 mg. of New Zealand butter, over long periods, as the sole source of vitamin A for rats, and found them adequate for maintenance and considerable growth,[5] but smaller doses were not tried. Moore [2] recently pointed out that the minimum dose of raw carrot was smaller than had been supposed. He found it to be 100 mg. daily or less. On 100 mg. two rats showed fair growth; the only rat which received 50 mg. died.

Very much smaller values have been obtained by McLaughlin [6] [7] who made a considerable examination of New Zealand spinach (*Tetragonia expansa*), investigating the value of leaves of different sizes. She found that, according to the size of the leaf, the dose needed to maintain life and promote some growth varied from 70 to 120 mg. per rat *per week*. Of prickly seeded spinach, 70 mg. weekly were found sufficient. These values are extremely small, but it is not very clear how completely McLaughlin's rats were depleted, and it is not easy to be certain, therefore, how far the dose was a full maintenance dose or not; her comparisons are valid for her own work, but are not certainly truly comparable with those of other workers.

We have made a few tests on fresh prickly seeded spinach, fresh cabbage, and New Zealand butter, from which it is evident that smaller amounts than had been supposed necessary of these foodstuffs also will suffice to maintain life in the rat. The results are very fragmentary, but are set out in the Table, together with the values obtained by the same method with two samples of carotene, one derived from spinach and one from carrots. Reference to the Table shows that two rats were maintained on 20 mg. and 30 mg. daily of fresh spinach respectively. A little growth was made on the 20 mg. dose, showing that even this was probably not quite minimal. The 20 mg. dose was tried because, according to the figures of Arnaud, quoted by Leroy S. Palmer in his book on "Carotinoids," it would represent a carotene

Table showing Growth of Rats on a Diet devoid of Vitamin A, after a Preliminary Depletion Period, on addition of various daily doses of Carotene, Spinach, Green Cabbage, and Butter.

Dosage was maintained for 28 days. The symbol + after the number of days of maintenance signifies that the animal appeared likely to survive longer when dosage was stopped.

Remarks.—*Died at end of experiment. †Failing at end of experiment. ‡Cured after failure on other material. Abbreviated experiment. §Huge calculi in bladder. ‖Cured after 20 mg. dose. ¶Failing at end of experiment. Calculi.

content of about 0·003 mg., a dose which, as already mentioned, is found by this method to be minimal.

With fresh cabbage two rats were maintained on a dose of 20 mg. daily, while a third failed on this dose, but was cured and grew normally on 80 mg. daily. With New Zealand butter one rat made normal growth with a daily dose of 56 mg., four maintained and made some growth on 28 mg., while on 14 mg. one failed and one survived.

If the minimum dose is taken as being the smallest dose upon which all the animals are able to survive, the above results give indications that the minimal daily rat dose of spinach is 20 mg. or less, of cabbage more than 20, but less than 80 mg., of New Zealand butter 28 mg. or less. Reference to the Table shows that the corresponding minimum daily dose of carotene by the same method is 0·003 mg. Too few rats were used in these experiments for the values to be taken as finally conclusive, but they are indicative, and we have found that clear-cut results can usually be obtained with three or four rats for each dose of material, and that doses differing from one another by 50 per cent. or possibly less can be differentiated. McLaughlin [6] was able to differentiate between doses which only differed by about 10 per cent., but the number of animals on each dose was large, usually about a dozen.

It thus appears that the minimum dose for many foodstuffs is considerably less than has been supposed, and that it can be ascertained with considerable accuracy, and without employing large groups of animals, by the biological technique based on maintenance of the rat rather than on growth. It is also suggested that the evaluation of foodstuffs might be standardised against the value of carotene, if a specification were agreed upon as to the properties—for instance, melting-point and colour-index—to be required from the carotene which should function as the standard. If a mapping out of the value of the commoner foodstuffs for vitamin A were carried out it would be an important step towards determining the adequacy or inadequacy of human dietaries in this respect. Attention has been focused lately on the possibility that a partial deficiency of vitamin A is not uncommon, and that a condition of latent deficiency disease results in which the individual is liable to infectious invasion of the mucous membrane, more particularly in the respiratory passages, as well as to other ills.[8] Accurate evaluation of a dietary, with the knowledge at present available, presents insurmountable obstacles, and verdicts as to adequacy or inadequacy of vitamin A are, except in extreme cases, quite conjectural.

WESTON-SUPER-MARE HOSPITAL: NURSES' HOME. A new nurses' home for the Weston-super-Mare Queen Alexandra Memorial Hospital was opened last week by Dr. G. H. Temple, the senior member of the honorary surgical and medical staff. The home contains 22 bedrooms and has the usual amenities. Application is being made to the General Nursing Council for the recognition of the hospital as a training school.

MEDICINE AND THE LAW.

Partnership Dispute.

SOME remarks on medical partnerships in "The Conduct of Medical Practice" may appropriately be repeated in view of recent litigation. Partnerships, it is observed, sometimes fail because the partners are temperamentally incapable of carrying on together. "When this occurs the partners cannot be too vehemently urged to keep out of the law-court." If they insist on going to law they will probably involve themselves in a distressing and expensive struggle which will injure them and perhaps discredit in the public eye the profession to which they belong. The recent litigation to which we refer was a slander action brought by one partner against another. It was stated by the plaintiff's counsel, in his opening speech, that the parties, who had been in partnership since 1911, had always been antipathetic in character and outlook, and for years there had been friction between them. The plaintiff, for instance, had complained of the way in which, while he was absent on holiday, the defendant had looked after his patients. In February, 1929, it was said, the plaintiff had an acute attack of gastritis as the result of overwork, and the defendant's attitude had been so unsympathetic as to suggest that the defendant thought the plaintiff was shamming. A few months later, when the plaintiff was under treatment by another practitioner, the defendant seems to have formed the opinion that the plaintiff was not ill at all, but was drugging himself with morphia. This suspicion influenced the defendant so strongly that, when the plaintiff was away in France for a holiday in August, he really believed that the plaintiff was not in France at all but was hanging about the neighbourhood so that he might slink into the house and satisfy his craving for drugs. There was no doubt that someone had been taking drugs from the dispensary cupboard. The defendant had marked the bottles and found many ounces of morphine missing between the end of August and the middle of October. But, when at last the defendant taxed the plaintiff with the taking of the drug, the plaintiff (who vigorously denied the allegation) discovered that a nurse who had access to the cupboard was the culprit. This unhappy woman turned out to be a drug addict; she was caught in the dispensary with the morphine bottle in one hand and the measure in the other. It thus became perfectly clear that the defendant's suspicions of the plaintiff had been mistaken. The accusation, however, had not made the parties any better friends and the plaintiff eventually brought an action for slander.

Now, if one partner should honestly believe that another partner is drugging himself improperly, and if the former communicates his suspicion in private to the latter, there is no slander because there has been no publication to a third party. In this particular case the matter had gone further. The regional inspector of the Ministry of Health had paid a routine visit in November, 1929, and to him the defendant had mentioned the disappearance of the drug and his suspicion against the plaintiff. In addition, the defendant had apparently made a similar communication to another practitioner who had acted as locum tenens in the plaintiff's absence in France, and who was negotiating with a view to entering the partnership in the plaintiff's place if the vacancy occurred. There was thus sufficient publication, but two further legal obstacles stood in the

plaintiff's way. It is a peculiarity of the law of slander (i.e., defamation by spoken, not by written, words) that words are ordinarily not actionable unless they were such as to cause appreciable damage for which compensation can be assessed. This alleged slander about the drug-taking was actionable only if it charged the plaintiff with the commission of a crime—e.g., the stealing of the drugs from the cupboard—or if it disparaged the plaintiff in the way of his profession as a medical practitioner; in either of those two cases the words would be actionable in themselves; but otherwise the plaintiff would have to prove that he had suffered special damage. The second obstacle was the defence of privilege. There are times when it is a duty to speak out frankly in disregard of the consequences. If a practitioner honestly thinks his partner is improperly drugging himself, he may be entitled to privilege if he speaks out in pursuance of his duty and to protect the partnership interests; he may also legitimately speak out to the Ministry of Health inspector if it is the inspector's duty to see that the supply of drugs is not misused. This defence of privilege can be destroyed if the defendant can be shown to have spoken out maliciously and to have been actuated by some wicked or indirect motive.

The judge held that all the statements which were made by the defendant were privileged; it was for the jury to say whether there was any malice which rebutted the privilege. These various legal issues are reflected in the four questions which Mr. Justice Horridge left to the special jury. The questions were put in duplicate to the jury in view of the alleged double publication to the locum tenens and the regional inspector. The jury gave the same answers in both cases and answered all four questions in the negative. The first two questions must have been the most difficult; they were (1) were the words spoken of the plaintiff as a doctor, and (2) did they impute to him any unfitness in his profession as a doctor? As already explained, the alleged slander would not be actionable unless the words referred to the plaintiff's conduct as a medical practitioner, and were such as would prejudice him in his profession. One would suppose that a reputation for addiction to drugs would hardly be a good advertisement for a doctor. However, the jury, after direction by the judge, quickly answered the two questions with the word "No." The next question was whether the words imputed a criminal offence. The defendant had been pressed in cross-examination with the suggestion that secretly taking drugs from the partnership supplies meant stealing; but he denied that he had intended any accusation of theft. "Any doctor," he said, "has the right to take any drugs from the partnership dispensary; it is the usual custom." The last question to the jury was whether the defendant was actuated by malice. This question, like the previous questions, having been answered by the jury in the negative, the defence prevailed all along the line. Judgment was accordingly entered for the defendant with costs.

Returning to the general reflections with which we began, we ask what good has this litigation done to the partners concerned? The plaintiff, naturally anxious to make it clear that the accusation of drug addiction was false, may have felt unwilling to forgo his legal remedy. He has lost his action and his costs will not be light. The defendant, who seems not to have expressed regret for his mistake until he was in the witness-box at the trial, has won his action but is shown to have made one singularly unfortunate diagnosis on inadequate grounds. The medical profession as a whole has perhaps not greatly suffered from the publicity which the dispute has obtained; on the other hand, it has no special reason to thank or congratulate the parties. In a situation intolerable through incompatibility of temperament, one simple remedy is a mutual agreement to dissolve the partnership. If in such contingencies the disposal of the goodwill or other partnership assets or the return of the purchase money is a stumbling-block, is there no arbitrator whom the parties can trust to give a reasonable common-sense decision? One of the risks of choosing the law-courts instead of an arbitrator is that litigation of this nature often ends in arbitration after all. Many judges, in such a case as we have described, press a settlement upon the parties rather than allow a regrettable personal squabble to occupy the time of the court. The resultant compromise may or may not satisfy plaintiff and defendant; it means that they submit in the end to the arbitration which they might have accepted in the beginning without the lawyer's bills and the publicity.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

THE following appointments are notified: Surg. Comdrs. J. S. Austin to *President*, for three months' post-graduate course; G. R. McCowen to *Victory*, for Haslar Hospital; and C. F. O. Sankey to *Warspite*.

ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg. Sub.-Lts. T. Colver and J. C. Livingstone to be Surg. Sub-Lts.

ROYAL ARMY MEDICAL CORPS.

Lt. (on prob.) J. Beggs resigns his commn.
Lt. E. S. O'Sullivan relinquishes his temp. commn.

ARMY DENTAL CORPS.

Maj. L. Somerville-Woodiwis relinquishes his commn. on appt. to a permanent commn. in the R.A.F.

TERRITORIAL ARMY.

Lt. L. N. Jackson to be Capt.
W. E. Tucker to be Lt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Capt. F. W. Bury, from Active List, to be Capt.

ROYAL AIR FORCE.

Medical Branch.—Proby. Surg. Lt. H.T. Rylance, R.N.V.R., is granted a temporary commission as a Flying Officer.
Dental Branch.—Squadron Leader P. E. Brown (Maj., Army Dental Corps) relinquishes his temporary commission on return to Army duty.

COLONIAL MEDICAL SERVICE.

Appointments as Medical Officers have been made as follows: Dr. W. C. E. Diamond, Malay States; Dr. D. P. Turner, Somaliland; and Dr. J. A. Loewenthal, Uganda.

MILLER GENERAL HOSPITAL.—At the annual meeting last week it was stated that 2200 in-patients were treated in 1929, the largest number on record; there were 192,000 out-patients. The massage, electrical, Swedish remedial, and ultra-violet ray department treated 73,492 patients. Last year's financial difficulties were alleviated by the grant of £12,000 from King Edward's Fund and generous help from others.

DUDLEY GUEST HOSPITAL.—Princess Mary last week opened a new wing which constitutes the first unit of an extension scheme which, including the remodelling of some of the existing wards, will cost £50,000. The new wing, including furnishing, will entail an expenditure of between £20,000 and £25,000, most of which has already been obtained, and will provide 54 additional beds. When the entire scheme is completed the hospital will contain 189 beds.

PUBLIC HEALTH SERVICES

HEALTH OF THE CITY OF LONDON.

Statistics.—Estimated population, 10,700. Birth-rate, 7·4. Death-rate, 14·0. Death-rates per 1000 of the population: tuberculosis, 0·37; cancer, 1·4; respiratory diseases with influenza, 2·5; heart disease, 4·4. Death-rates per 1000 births: infants, 63; young (1–5 years) children, 13; mothers from childbirth, 0.

THE smallness of the figures causes the rates in the City to be liable to yearly fluctuation. Dr. W. M. Willoughby shows that an unusual proportion of the population live under rather special conditions. Thus 910 live in artisan's dwellings erected by the late Commissioners of Sewers and the Corporation. The birth-rate in these dwellings was 7·7 and the death-rate 12·1. The residents used the baths provided for them at the rate of 15 per head per annum. Registered houses let in lodgings provide for 448, with an average of 2·3 persons per tenement. Eleven blocks of self-contained dwellings provide for 1217 persons, with an average of 2·8 persons per tenement.

The attention of the Fishmongers' Company was drawn to a source of winkles suspected of causing a case of enteric fever. Of 48 samples of bread and butter, one informal sample was found to contain 40 per cent. of foreign fat. Of 26 samples of cream, one contained 95 per cent. of fat not derived from milk. In two cases samples of sauce were found to contain copper sulphate, which investigation showed to be due to defective copper pans. In two cases of adulterated milk the retailer requested that samples should be taken in course of delivery to him. The samples had to be taken by an outside authority and were certified to be genuine. Proceedings were successfully instituted against both retailers. Two milk vendors were convicted of bottling milk in the street. One of them, who had been previously cautioned, was fined £40 and the other £5. There was a decrease of 27,000 tons in imported beef as compared with the previous year. Argentina supplied 77 per cent. Mutton and lamb were about the same in amount as last year, and Argentina made good the decreases from New Zealand and Uruguay. The proportion of British diseased meat discovered in the markets rather increases than lessens, and Dr. Willoughby points out that meat inspection in this country cannot be complete until all carcasses and organs are examined at the places of slaughter, and the meat which is passed is officially stamped.

The investigation of tuberculosis in pigs from avian infection has been continued. Dr. Stanley Griffith and Mr. R. L. Cornell, M.R.C.V.S., have typed the tubercle bacilli from the lesions in pig's carcasses. Out of 95 submaxillary lymph glands successively examined, one showed the human type of bacillus, and of the others two-thirds were bovine and one-third avian in origin. Their findings corroborate those of workers in America and on the Continent, and support the recommendation that pigs and poultry should not be allowed on the same run. Experiments indicate that the more rapid the chilling of meat, especially beef, the better is the quality. A new discovery is that meat can be cooked directly from the frozen condition, and is much more tender and palatable than when cooked after thawing. The mutton-importing countries are improving their methods of examination in order to lessen the amount condemned in the London market for caseous lymphadenitis. During the year 28 naval officers were trained in meat inspection at the central markets, and the London School of Hygiene and Tropical Medicine was added to the institutions according facilities for teaching purposes. Progress continues to be made in securing clean methods in transport and handling of meat.

During the warm weather there were many complaints of offensive smells from street gullies and sewer ventilators. To deal with the former old pattern gullies are being replaced by a more up-to-date design. As regards the sewers, it has been the practice to seal the ventilators on the receipt of complaints, but in view of the serious explosion in an adjoining area in 1928 this practice has been discontinued. It is difficult, however, to obtain the permission of owners to allow ventilating shafts to be erected against their buildings. The size of the pigeon population has been again complained of and a campaign is to be conducted during the current year similar to that of 1928. Rat repression and rat proofing continue vigorously, and the brown rat is not in evidence so much as the black.

REPORTS OF SCHOOL MEDICAL OFFICERS.

—	No. on roll.	Average attendance.	Routine inspections.	Special exams. and reinspections.	Percentage of defects.
Bootle	11,628	10,443	3697	18,272	25·4
Wiltshire ..	28,104	25,245	9610	12,319	25·15

Bootle.

Dr. F. T. H. Wood draws attention to the twofold responsibility of the education authority in respect of the physical welfare of school-children: (1) to give all kinds of medical care; (2) to assist sound physical development and to afford instruction in the laws of health. In both directions the duties are being fulfilled at Bootle, where the need for assistance in carrying out the second has led to the appointment of a master and mistress of physical training. These full-time instructors, while primarily engaged in the training of secondary school pupils, have a portion of their time allotted to elementary schools; their expert knowledge should enhance the value of the training given, supplemented by out-of-school activities, such as play centres, the recently acquired playing field, school sport, and swimming. The instructors' work is of special importance in the secondary schools where the defects fall largely under the three headings of defects of teeth, defective vision, and deformities; the figures for all other conditions in Dr. Wood's table are relatively small, due no doubt to the care of the parents and the family doctor. Abnormalities are treated at the clinic for remedial exercises, which was attended by 440 children, of whom 95 were below school age. The conditions treated included mouth breathing, spinal curvature, rickets, and flat-foot, as well as more serious defects resulting from infantile paralysis and fractures. Turning to general medical care, the total number of examinations this year shows a substantial increase in spite of a slight fall in the school population. The appointment of an additional woman medical officer will make it possible to give more attention to pre-school children, which Dr. Wood regards as important in agreement with the dictum of Dr. C. J. Thomas that the infants' departments of schools are "receivers of damaged goods." It is proposed to establish two nursery schools and to make more use of the school clinics for pre-school children. A loss to the staff is the removal of Dr. A. B. Williamson, whose investigation of rheumatism has led him to conclude: (1) The percentage of rheumatism in Bootle is 1·8. (2) Girls are more liable to be affected with the choreic form of the disease. (3) The school distribution and the social status of the cases bear out the fact that the condition is most prevalent among the children of the skilled artisan class. (4) There is no evidence to suggest the existence of a so-called rheumatic type of child.

(5) There appears to be no association between rheumatism and dental decay. (6) The increased family incidence of the disease (30 per cent.) may be due (*a*) to the influence of similar environmental conditions, or (*b*) to an hereditary predisposition, or (*c*) to a carrier infection. (7) Evidence of a relationship between rheumatism and damp dwellings is inconclusive. (8) There seems to be a definite association between tonsillitis and rheumatic infection, and every child subject to attacks of tonsillitis should be observed closely for commencing signs of rheumatism. (9) Tonsillectomy appears to be justified in all non-choreic cases, but to be of most value it must be done early in the disease. The operation has no obvious effect in cases with chorea. The operation should not be performed until a previous attack of tonsillitis has completely subsided. (10) Care and supervision at a rheumatic clinic are not enough to prevent relapses. Institutional and convalescent treatment are probably the best means we have at present of combating the disease. (11) Every child presenting vague unaccountable signs of ill-health should be examined periodically with special reference to its heart. The conclusions which rest on a sound basis agree with those of similar inquiries except as to the correlation with poverty. The only obvious weakness in the service at Bootle is the absence of special schools.

Wiltshire.

Dr. C. E. Tangye's report is typical of that of a well-ordered but not exceptional county. The staff has been strengthened by the appointment of a part-time woman doctor and an additional nurse. Dr. Jean Murray is also part-time medical officer of health for a district, and this principle of combining appointments has been definitely approved by the county committees concerned. It helps to coördinate school and public health work, as does the appointment of school nurses who are also health visitors. The scheme for the supervision of all children up to school age is said to be developing, but no specific mention is made of facilities for their treatment. The medical inspectors have investigated the sanitation and hygiene of the schools and improvements have resulted. Following a lead given by the London County Council the time-honoured sloping-topped desk, which had many disadvantages, has been given up in favour of a new type of flat-topped desk. An apparent increase in the numbers of under-nourished children is not to be taken to indicate any general lowering in the standard of nutrition. There is now a regular system of treatment by giving cod-liver oil and milk, and the inspectors class children as ill-nourished if they would be likely to benefit by this addition to their diet. Cleanliness has shown striking improvement, the number of children found unclean last year being only 2032, compared with 4711 in the previous year. The decrease reflects great credit on the school nurses, the more so as no cleansing stations are provided. The nurses give demonstrations and advice to mothers, and provide special combs at cost price. Clinics for ear, throat, and nose affections have been established throughout the county. Mr. Miles Atkinson reports that recurrence of aural infection can almost always be prevented by removal of infected tonsils and adenoids if the tympanic membrane is intact at the time of operation; that cases of otorrhœa of recent origin with anterior perforations indicating disease of the throat can be cleared up by an operation on the throat without other treatment than cleansing of the ear, and that in most cases the perforation will heal; that cases with a central perforation may be dried, but the tympanic membrane is unlikely to heal; and that cases with an almost total loss of the tympanic membrane with long-standing otorrhœa, especially when it follows one of the specific fevers, are unlikely to dry without some form of mastoid operation. Aural surgeons would no doubt largely agree with him that operation, when indicated, should always be performed, but they would add that ionisation is beneficial in many cases after operation and occasionally even before it. Dental work is satisfactory; 70 per cent. of the children requiring treatment received it; in the northern area the percentage was over 82. The committee hopes for still better figures, and is recommending the appointment of another dentist and the promotion of Mr. W. H. Liebow, L.D.S., to be senior dentist in charge of the scheme. As in many other rural areas, there are no special schools, but the Wilts. authorities have made an effort to secure accommodation in residential schools.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED DEC. 6TH, 1930.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 95 (last week 160); scarlet fever, 2188; diphtheria, 1529; enteric fever, 28; pneumonia, 1010; puerperal fever, 55; puerperal pyrexia, 112; cerebro-spinal fever, 12; acute poliomyelitis, 7; acute polio-encephalitis, 1; encephalitis lethargica, 13; dysentery, 24; ophthalmia neonatorum, 93. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Dec. 9th–10th was as follows:—Small-pox, 206 under treatment, 5 under observation (last week 236 and 2 respectively); scarlet fever, 1925; diphtheria, 2163; enteric fever, 13; measles, 80; whooping-cough, 110; puerperal fever, 21 (plus 5 babies); encephalitis lethargica, 121; poliomyelitis, 1; "other diseases," 49. At St. Margaret's Hospital there were 15 babies, plus 5 mothers with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there were 2 deaths from small-pox, 3 (0) from enteric fever, 45 (2) from measles, 6 (2) from scarlet fever, 17 (2) from whooping-cough, 31 (7) from diphtheria, 49 (10) from diarrhœa and enteritis under two years, and 43 (8) from influenza. The figures in parentheses are those for London itself.

The fatal cases provisionally classified to small-pox were assigned to Wood Green U.D. and Dagenham U.D. Details of the former were given in our issue of Dec. 6th (p. 1260). The fatal cases of enteric fever were reported from Hastings, Bury, and Hull. Ten deaths from measles were reported from Liverpool, 8 from Hull, 6 from Swansea, 5 from Bristol, and 3 from Birmingham (Dublin reported 14 cases in the same week). Five fatal cases of diphtheria occurred at Birmingham and 3 at Liverpool. Diarrhœa accounted for 5 deaths at Manchester and 4 at Liverpool.

The number of stillbirths notified during the week was 281 (corresponding to a rate of 41 per 1000 births), including 43 in London.

A "PRUDENTIAL" BED.—The Prudential Assurance Company has promised an annual subscription of £500 for the endowment of a maternity bed in St. Mary's Hospital, London. The money is being given in recognition of the hospital's maternity work, "and as a manifestation of interest in the movement for better maternity services throughout the country."

"MOORFIELDS HOSPITAL" EXTENSION.—Prince Arthur of Connaught last week opened new private wards and nurses' quarters at the Royal London Ophthalmic Hospital, City-road, E., of which he is President. The block of private wards contains 17 rooms and a theatre, and 39 rooms have been added to the nurses' quarters. Including the addition of a floor to the existing building, the work has cost £39,000.

A HOSPITAL "DRAW."—For the last ten years Mr. William Charlton, a stonemason in the employment of Newcastle-on-Tyne Corporation, has organised an annual "draw" for the benefit of Newcastle Eye Hospital as a mark of his gratitude as a former patient. Last year £550 was raised in this way, but last week the police, acting upon instructions from the Home Office, stopped the sale of tickets and the "draw" has consequently been abandoned.

CORRESPONDENCE

VALUE OF RAMISECTION IN CASES OF SPASTIC WEAKNESS.

To the Editor of THE LANCET.

SIR,—In your issue of to-day Mr. Bankart, under this heading, says that "Lord Moynihan was unfortunate in his choice of the researches of Hunter and Royle to illustrate 'the somnolence of physiologists.'" Using this as preamble, he occupies two columns of THE LANCET in a dissertation upon the value of "ramisection in cases of spastic weakness," to which I quite deliberately made no reference whatever. I wrote:—

"Just as physicians, to use Sir William Osler's phrase, were 'caught napping' by surgeons who asserted the frequency and created or amplified our acquaintance with the symptoms of gastric and duodenal ulcer, and of cholelithiasis, so the physiologists have similarly had their somnolence proclaimed by the researches of Royle and Hunter, Wade of Sydney, Robertson of Toronto, Judd, Adson, Learmonth, and others, as to the sympathetic nervous system, and its influence upon maladies of men so diverse as Raynaud's disease, Hirschsprung's disease, endarteritis obliterans, and retinitis pigmentosa. Learmonth's recent investigations carry the possibilities of helpful or remedial surgery still further."

The work of Hunter and Royle, whatever may prove to be its value in the very restricted field of surgery with which Mr. Bankart is here concerned, was, as everyone should know, the inspiration of Wade in his valuable pioneer work upon the intestines, and was the direct incentive not only to the new work of the surgeons whose names I quote, but to fresh and eager anatomical and physiological inquiry in many parts of the world. It is not to Royle's early operative work, but to his fecund influence upon the surgery of the sympathetic system that I referred in the paragraph which Mr. Bankart curtailed. By so doing he has failed to appreciate the full significance both of the carefully ordered sequence of names and of the special list of diseases selected for enumeration. With wider vision than Mr. Bankart allows himself, I therefore still regard my choice of illustration as singularly happy and most appropriate.

I am, Sir, yours faithfully,

Portland-place, W., Dec. 13th, 1930. MOYNIHAN.

PASTEURISATION OF MILK.

To the Editor of THE LANCET.

SIR,—The addition of pasteurised or separated milk to the ordinary mixed diet of school-children has been proved of enormous value by the work of Corry Mann and other observers. That fact, however, does not affect the question of the true nutritional value of milk. The study of the problem as it stands at the present time reveals the fact that the most enlightened thinkers in those countries which have adopted pasteurisation as the main plank of milk selling are recognising more and more clearly that treated milk is not of equal value to fresh milk, and this becomes particularly clear when these different types of milk are given to young children; that is to say, those whose food-supply is strictly limited.

The truth of this probability is gradually emerging as the result of researches which are being carried out in the United States and in Holland. In this country, up to the present time, no comparable work has yet been done, and it is urgently required. It would seem, therefore, to be a great pity to suggest that in future Certified milk shall be the only fresh milk-supply; for in practice the cost of this milk makes it a luxury article which can be consumed only by those with substantial incomes. The adoption of such a policy, therefore, will reduce London, for instance, to a position comparable with that of New York, where not more than 2 per cent. of the total milk-supply is sold as fresh milk, and those who are in most need of it are unable to get it. In England, on the other hand, we have at present not only Certified, but also Grade A (Tuberculin Tested) milk, which is being sold in increasing quantities, particularly in the East End of London, and in many provincial towns. In the East End of London such milk is sold at a price which the working classes are obviously prepared to pay, although one hopes as time goes on it may still be further reduced from 2*d.* a quart extra, which it costs at present, to perhaps not more than 1*d.* extra, the price that is paid in one district of London, Reading, and some other provincial towns. Experience has shown that it is quite possible to put milk of this character into the house of the consumer, even in London, satisfactorily. In doing so the best interests of the consumer and of the farmer are served, for the one gets untreated milk and the other a fairer share of the monies which are paid for it. It would appear, therefore, that it is very important that we shall preserve an open market for the sale of fresh milk from licensed tubercle free herds at a reasonable price, until such time as we are satisfied that other forms of milk possess the nutritive value that all of us desire in the best interests of the health of the nation.

To pasteurise the whole milk-supply of the country is impossible, until such time as the whole population has become urban. With all due deference to the very distinguished men who have appealed for universal pasteurisation of milk except Certified milk, I would suggest that even in spite of their practical knowledge of dairy farms and the milk industry, the question should be approached with very great care and that the tampering with one of Nature's foods, except to insist on its being provided from healthy cows under perfectly clean conditions, may, with increasing knowledge be found to be putting the hands of the clock back, and eventually doing more harm than good to the health of the nation.—I am, Sir, yours faithfully,

C. MADDOCK,
Hon. Sec., The Certified and Grade A (Tuberculin Tested) Milk Producers' Association.

16, Ormond-yard, York-street, London, S.W., Dec. 15th, 1930.

To the Editor of THE LANCET.

SIR,—I welcome the letter by Lord Dawson, Sir John Robertson, and others, advocating the universal adoption of pasteurisation of milk. At one time I was doubtful as to the desirability of this course, as I feared it might militate against the general adoption of the principle of milk from tuberculin-tested cows, which I believed was the more excellent way. However, having been reluctantly forced to the conclusion that the latter principle, however ideal, is not likely to be realised, at any rate during the present generation, I now feel that universal pasteurisation of all milk other than "Certified" or "Grade A (Tuberculin Tested)" is the only

satisfactory alternative, and the sooner it comes the better. I would suggest that it would be quite feasible to make efficient pasteurisation compulsory provided sufficient notice were given to enable all milk purveyors to make the necessary arrangements and install the necessary plant. Already a very large proportion of the milk-supply of large towns is pasteurised although not always sold as such.

I am, Sir, yours faithfully,

C. KILLICK MILLARD,
Medical Officer of Health, Leicester.

Health Offices, Leicester, Dec. 15th, 1930.

To the Editor of THE LANCET.

SIR,—I am in entire agreement, so far as they go, with the signatories to the letter on pasteurisation of milk in your last issue (p. 1315), but why do they draw the line at "Certified milk"? Has not Certified milk produced undulant fever and septic sore-throat? It cannot be too widely known that no raw milk, certified or uncertified, can be regarded as safe. Improve the milk at the source by all means and all the time, but to neglect to pasteurise it is only asking for trouble. There is nothing sacrosanct about "Certified milk" and its pasteurisation will do it good. I am, Sir, yours faithfully,

J. C. G. LEDINGHAM.

Lister Institute, London, Dec. 13th, 1930.

To the Editor of THE LANCET.

SIR,—The signatories to the letter on this subject are of the opinion that the entire milk-supply—excepting "Certified milk"—should be pasteurised. It would be of great interest if they would explain what advantage would accrue to the general public if pasteurisation of Grade "A" (Tuberculin Tested) milk were made compulsory. The advantage to large wholesale pasteurising firms is, of course, obvious.

I am, Sir, yours faithfully,

D. M. CONNAN.

Public Health Department, Town Hall, Bermondsey, S.E., Dec. 12th, 1930.

HYPOSPADIAS.

To the Editor of THE LANCET.

SIR,—To the recent proceedings at the staff meetings of the Mayo Clinic, at Rochester, Minnesota (Nov. 5th, p. 315), Dr. Hugh Cabot made a communication on the plastic operation for epispadias, hypospadias, and urethral stricture; to his remarks on hypospadias I wish to refer, as the opinion expressed of surgical interference seems to me incorrect.

There is still a widespread opinion that hypospadias is not really amenable to treatment, and that, although many operations have been invented by many surgeons, all of these give such poor results that they are hardly worth doing. For example, the last case which I completed, a case of complete hypospadias with cleft scrotum, had been told by a relative, who was on the senior staff of a large metropolitan hospital, that nothing could be done for him. This attitude is unfortunate because this deformity is a very serious one. It is true that the patient can pass his urine and has complete control, but only a superficial view would regard the condition of no great consequence. To the patient it certainly is a serious disability; he is nervous lest his deformity should be observed, he cannot micturate, as a rule, in the normal way, and he feels different to his fellows. In addition there is a risk that he may drift into sexual irregularity.

It is true, that in all the cases which have come under my personal observation, that is to say, as far as I could observe, there has only been one in which the psychical outlook has been abnormal; I consider that the deplorable habits of some adult pseudo-hermaphrodites are secondarily acquired. Were it only because of this risk, the treatment is worth while. This is specially the case when there has been an error in determining the sex of the patient, who should be made to resemble externally the sex to which he really belongs when he assumes the characteristic garments.

It is very important in cases of sex error to be quite sure that there has been an error, and this will generally necessitate examination under an anæsthetic. I have had two undoubted girls sent to me for the cure of hypospadias. In one of these the labia were united posteriorly giving a very typical picture of an ordinary cleft scrotum. On dividing this union a vagina was revealed leading to a normal uterus. In both of these cases the clitoris was unusually large. In common with all surgeons I have had the gratification of seeing the pleasure of a patient after recovery from an operation, but I have never seen any class of patients whose delight has been so manifest as that in which the deformity of hypospadias has been corrected; and this even when the patient is only a little boy.

Prof. Cabot seems to share the common pessimism, which I would venture to state is not justified. It is possible by the methods which I published, first in 1913 (THE LANCET, 1913, i., 447) and later in slightly greater detail, and after fuller trial in my Hunterian Lecture (THE LANCET, 1926, i., 323), to perform an operation which is really worth while doing. In this latter communication photographs were published of adults who had been operated upon in childhood with completely satisfactory results—that is, the penis is of average size, straight or with only the slightest curve on erection, with the opening of the urethra at the end of the glans. I have operated on a good many cases since 1927 with uniform results. In no case has there been failure to restore the urethra, although in some cases secondary operations to close fistulæ have been needed.

The principle of the operation, as described in full detail in the paper quoted above, is based on Duplay's method; but before attempting to reform the urethra, the prepuce is transplanted along the sides of the penis so as to broaden the organ and provide enough tissue for the final closure. The straightening of the penis is obtained, not by dividing bands, but by dissecting up the whole of the contracted urethra. Prof. Cabot states that in the very minor cases in which the cleft in the urethra does not extend beyond the glans, no operation should be performed. This is often true, but the reason for not operating is not that the cleft cannot be closed; for, although I have had failure of union in other parts of the urethra, it is a curious fact that I have never failed to get union of the glandular part at the first attempt. The operation can be done and is worth doing at any rate in the type of case where there is stenosis of the displaced meatus, since the slitting up of this displaces the opening of the urethra a good deal farther back. It is equally possible to deal with the most advanced cases. I have operated upon four cases of sex error; two of these had been brought up as girls until they were adolescent, one till he was four years old and in one case the error had only persisted for a few months.

There is indeed no difficulty in the operation and

several surgeons could testify to their success in the procedure; of course it must be a delicate operation, requiring fine sutures and careful handling—I now use fine black silk for the mucous membrane and ophthalmic silkworm gut for the skin. I have never found it necessary, as Prof. Cabot advises, to divert the stream either by perineal or suprapubic drainage. With careful suturing and by keeping the parts moist with flavine 1–3000 union takes place readily, and, if fistulæ form, they can always be closed. The operation which I have described has this advantage that no tissue is removed and, if union fails to take place at the first attempt, it is always possible to make another in two or three months, after the scar has softened.

I am, Sir, yours faithfully,

ARTHUR EDMUNDS.

Queen Anne-street, W., Dec. 15th, 1930.

NEPHROSIS AND ŒDEMA.

To the Editor of THE LANCET.

SIR,—The article by Dr. T. Izod Bennett, Prof. E. C. Dodds, and Dr. J. D. Robertson in your issue of Nov. 8th (p. 1006) is very interesting and instructive. Some of the conclusions, however, require comment. Briefly stated, the authors present two points of importance:—

First, that lowering of the plasma protein, even when due to other than renal causes, may cause œdema.

Secondly, that the absence of renal lesions in cases with œdema resulting from extrarenal loss of protein speaks against the "diabetes albuminuricus" theory of nephrosis.

With the first point I am in hearty accord. While the material presented is not wholly illustrative of this principle, it confirms the idea which I first propounded many years ago, and which now seems to be a well-established fact.

From the second point I differ emphatically. In formulating the theory of "diabetes albuminuricus" I never stated or believed that lowering of the blood protein in itself is the cause of renal lesions. I stated solely that *the renal lesions in nephrosis were not the cause of the albuminuria*—which is a very different thing. The confusion of these authors on this point apparently arises from the attempt to correlate the work and conclusions of Barker and Kirk, who, as others have done before them, found that the repeated removal of plasma causes œdema; and, in addition, that dogs so treated ultimately show changes in the kidneys which they claim resemble the renal changes of chronic nephrosis. While this observation of Barker and Kirk may be of significance and point to the influence of nutritional deficiency upon various organs and tissues, including the kidney, *the work requires confirmation, not only in respect to the occurrence of renal lesions following plasmapheresis, but also that the lesions so produced do actually resemble the changes observed in the kidneys of chronic nephrosis in man.* Moreover, the conclusions of Barker and Kirk relative to the renal lesions have nothing in common with my views in regard to the ætiology and pathogenesis of nephrosis, particularly as expressed in the concept "diabetes albuminuricus."

Bennett and his collaborators liken the conditions obtained in their clinical cases to the plasmapheresis experiments of Barker and Kirk, but they fail to find any renal lesions; hence they say:—

"We must therefore assume that in the human subject the diminution of plasma proteins, even for a considerable time, does not produce changes in the kidney.

"The importance of this," they continue, "in relationship to the ætiology of nephrosis is, we feel, very great. The 'diabetes albuminuricus' theory ascribes the cause of nephrosis to a modification in the protein molecule rendering it permeable to the kidney, with the result that massive loss occurs in the urine. Œdema then results and the renal changes which occur have been thought to be due to the loss of plasma proteins. Unless it be argued that the mere passage of the abnormal protein through the kidney is capable of producing renal lesions, it would appear that this argument falls to the ground, since extrarenal plasmapheresis in man does not damage the kidney. This forms a strong argument in favour of the view that the kidney is at least one of the primary seats of damage in nephrosis, and that the renal lesion causes the alteration in the constitution of the plasma proteins, and not vice versa."

The loss of protein from the blood through experimental or spontaneous plasmapheresis (effusions into the serous cavities) is totally different from that resulting from excretion of protein by the kidneys. The formation of effusions (ascites), such as these authors have observed, is due either to inflammatory or local static disturbances, and the process involved is one of simple filtration of blood plasma. The proteinuria of chronic nephrosis is of a different nature and is, I believe, an instance of selective and preferential excretion. One need but compare the composition of the urinary proteins of any case of nephrosis with what Bennett, and his co-workers found in the serous effusions of their cases, and the difference becomes at once apparent. We must, therefore, assume that the proteinuria of chronic nephrosis has back of it some alteration in the biochemistry of the plasma proteins themselves.

Proteinuria occurs either as a result of renal damage or because the proteins are abnormal in character, and hence are removed as foreign substances. *Histopathology has thus far failed to account for the proteinuria of chronic nephrosis*, and the conclusion (from all the evidence presented by this disease) is wholly inescapable that this proteinuria is of extrarenal origin—due in all probability to a biochemical change in the proteins themselves. That proteins which are foreign to the body can be excreted by normal kidneys is well known. Hæmoglobinuria and albumosuria afford us two striking examples of this fact. There is some evidence also that the continued excretion of foreign protein can ultimately damage the kidney. The profound renal changes in Bence-Jones albumosuria are well recognised, and this, we know, is primarily an extrarenal disease.

The absence of kidney lesions in the cases cited by Bennett and his collaborators is as it should be. The mere loss of protein from the blood through channels other than the kidneys is not in itself sufficient cause for alteration in the kidney structure. One cannot as yet offer a satisfactory explanation for the kidney changes observed in human nephrosis. It is justifiable, however, to state that they constitute purely a secondary phenomenon and at times may be practically absent. I have recently seen demonstrated by a very competent pathologist the kidneys from a case of nephrosis in a child, which showed no more deviation from the healthy state than is generally to be seen in the kidneys in any long-continued wasting illness. It must also be remembered that in any long-continued lipæmia there may be storage of lipoid in the renal epithelium affecting the configuration of the cells. It is noteworthy that in none of the cases presented by Bennett and his collaborators was any lipæmia at hand.

If we analyse the evidence and the arguments which Bennett and his co-workers present we must conclude that these account for the occurrence of œdema, but that they have no bearing on the question of the pathogenesis of nephrosis.

I am, Sir, yours faithfully,

New York, Dec. 3rd, 1930. ALBERT A. EPSTEIN.

AN X RAY DEMONSTRATION.

To the Editor of THE LANCET.

SIR,—The publication of Dr. A. E. Barclay's Silvanus P. Thompson lecture in your last issue makes me think that some of your readers would like to be reminded that we owe to Prof. Thompson the first public medical demonstration of X rays in this country. Early in 1896 the Clinical Society of London invited him to tell the members about this new discovery. He kindly said he would, and a special meeting was held in the Society's rooms in Hanover-square on March 30th, 1896. Nearly 400 members, THE LANCET tells us,[1] were present—that is, almost four-fifths of them. The report of the Council says the meeting "was most successful, and a vote of thanks was unanimously accorded to Prof. Thompson for his great kindness." The audience was thrilled, most seeing for the first time actual prints of bones and pieces of metal. Silvanus Thompson was a prince among lecturers. I have never heard a better demonstration or attended a more memorable medical meeting.—I am, Sir, yours faithfully,

W. HALE-WHITE,
Hon. Secretary, Clinical Society of London, 1893–96.

Dec. 15th, 1930.

RESISTANCE TO TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—Dr. Burrell suggests in his Mitchell lecture that the resistance resulting from tuberculous infection is similar in nature to the tolerance acquired to drugs like morphia and alcohol, and is different in kind from the immunity to small-pox which results from successful vaccination. He concludes that it is wrong to attempt to protect by means of tubercle bacilli and that the correct procedure is to eliminate infection altogether or at least to dilute it as far as possible.

In these countries the first alternative is impracticable, so the second method—i.e., to dilute infection as far as possible—is the ideal to be aimed at. But the results which may be achieved by this latter method are exactly the results claimed by those who hold the infection-immunity-theory. And there appears to be a mass of evidence to support their views. For instance, Dr. Burrell mentions the difference in the results of infection amongst races where tuberculosis is not endemic and the results observed amongst civilised races. Also, not a single child born in Papworth Village Settlement has ever shown signs of tuberculosis, although the opportunities for juvenile infection must necessarily be very extensive. Post hoc or propter hoc, these children have acquired an unusual degree of resistance. Is it to be explained that they have merely become tolerant as the drug addict becomes tolerant? If so, this tolerance should be associated with stigmata analogous to those of the drug addict. Yet such is by no means the case. Nor has it been observed that persons who have successfully resisted infection are any the worse from the "tolerance" they have acquired. Does it not appear more likely that this resistance is, in fact, of the same nature as the immunity acquired towards other infectious diseases?

But if protection results from mild infection, one must explain why patients with mild tuberculous lesions, such as a small pleural effusion, are more liable to a recrudescence of active disease than others. Dr. R. C. Wingfield advances a very attractive hypothesis which goes far to explain this apparent anomaly. According to this theory resistance to tuberculosis is two-fold—namely, bacteriolytic and antitoxic. The bacteriolytic type brings about the death of the bacillus and terminates all its activities. The antitoxic type does not kill the bacillus but merely tends to counteract its toxic action. A person who possesses the first, or both, types is adequately protected, whereas one possessing only the antitoxic type is only partially protected, and is liable to a recrudescence of the infection.

Is it possible that the difference between the resistance to small-pox and the resistance to tuberculosis is a difference in degree, not in kind, and that the difference is merely due to the difference in the antigenic properties of the infecting material in each case?—I am, Sir, yours faithfully,

JAMES J. CONNOLLY.

Peamount Sanatorium, Co. Dublin, Dec. 15th, 1930.

[1] THE LANCET, 1896, i., 935.

OBITUARY

WILLIAM MACLEAN, M.B. Edin., D.P.H.

Dr. William Maclean, county medical officer of health for Ross and Cromarty, died at Dingwall on Dec. 10th after a brief illness. For the last 20 years he had never been robust, but had continued his work with ardour, and exercised to the last a profound influence over the development of medicine in the North of Scotland. He was educated at Dingwall and Inverness and later at Edinburgh University; in his younger days he was an accomplished classic, and always placed Gaelic beside Latin and Greek. After graduating in medicine in 1892 he went into practice as assistant to Dr. Bruce of Dingwall, and later in the old cathedral town of Fortrose. During these years was laid the foundation of his exceptional learning in prehistoric archæology. He discovered and investigated a settlement of the Mesozoic age in a cave near Rosemarkie, and to the end of his life retained a specialist's knowledge of this department. In 1908 he was appointed superintendent of the newly opened Seaforth Sanatorium, then the first institution of its kind in the North of Scotland. With this began his interest in public health, and in 1920 he succeeded Dr. Bruce as chief medical officer for the county. As an organiser of medical services he moved with ease among the developments of recent years. Few lawyers could surpass him in interpreting an Act of Parliament and his advice was sought repeatedly by the Department of Health. He was a prominent member, and for a time chairman of the consultative committee on the Highlands and Islands.

"In all gatherings of the profession," writes a colleague, "Maclean exercised a unique personal ascendency. He had the habit of stating a case with tempestuous frankness that was never in the least confused. In public speech the most direct of men, yet he made not even temporary enemies. He meddled in no controversies, and with supreme intellectual independence he would belong to no party. His experience had given him an immense reverence for the ethics of medicine. He feared the increasing mechanisation of our calling, although he was the first to test any fresh device and seemed to assimilate every modern procedure that appeared.

He was a man devoid of all pretensions. He had the secret of simplicity and cared little for his reputation and nothing at all for fame. Always one had a sense of the fascinating duality of his nature; the combination of fundamental sympathy towards the average man, with the loftiest intellectual capacity. His most characteristic moments were when discoursing upon some intricate problem that lay near his mind. It might be the origin of the Iberians, or the style of Hilaire Belloc, a clinical difficulty, a new salmon fly he had invented or a flint arrow head he had found in a field. A torrent of vivid expressions poured out like champagne. An inscrutable and charming smile followed, while he would listen without impatience to one's immature argument. Alas, that there was no Boswell to record these memorable conversations! For Maclean had a horror of dilettantism and could never be persuaded to publish.

"Estimated by ordinary achievement, his life was that of any conscientious worker. But his own peculiar contribution to the betterment of social and professional life cannot so be measured, and the tradition he left will be felt as in the years his work unfolds. For he never seemed to be old. He did not set out to influence others or to teach his assistants. They followed him instinctively and prized his example."

Dr. Maclean married Louise Fowler Grant. He leaves no family.

THE LATE LIEUT.-COL. N. S. SIMPSON, I.M.S.

Lieut.-Colonel W. G. Hamilton, I.M.S. (retd.), writes: "I should like to pay a short tribute to the memory of Lieut.-Colonel N. S. Simpson who was brutally murdered in his office at Writers' Buildings, Calcutta, on Dec. 8th. Colonel Simpson succeeded me as inspector-general of prisons in Bengal in October, 1929, after we had worked together in close association for several years. I always found him a loyal colleague and a staunch friend. He was a humane man, holding enlightened and very progressive views on the treatment of prisoners. In the summer of 1929, when he was convalescing from a severe attack of enteric fever, he studied the English prison system while on leave in this country. He kept his medical knowledge up to date and did good work in investigating the incidence of hookworm amongst the prison population of Bengal. He had a good eye for all ball games and was one of the best amateur billiard players I have known."

PANEL AND CONTRACT PRACTICE

A German Critic of Health Insurance.

Dr. Erwin Liek, a surgeon in Danzig, has written a book called "The Doctor's Mission" [1] in which he deplores the damage done to Germany by various forms of social insurance.

At present, he says, sickness insurance does not fulfil the object of its founders—namely, to treat and cure disease. On the contrary, it has become a means of obtaining doles rather than health, and the "will to be well" is everywhere undermined because a medical certificate means pay without work. The system weakens the manliness of the people and causes their physical and moral degeneration. "As soon as men and women have gratuitous medical and surgical treatment thrust upon them they are apt to search their bodies for signs and symptoms of diseases as carefully as a monkey searches for fleas." Thousands say to themselves, "As I am insured I must see to it that I receive every possible benefit I can obtain," and the case-books of panel doctors show that they are overwhelmed with ridiculous trivialities. Panel doctoring produces and carefully nourishes general neurasthenia and hypochondriasis, and two-thirds of it is superfluous. Where true disease is present "we notice immediately and without exception that the process of healing and the time of cure are greatly extended as soon as an individual who previously was uninsured has become insured under the social insurance scheme."

National insurance, in Dr. Liek's opinion, has destroyed the natural and normal relations between doctor and patient. With a private patient the doctor's only concern is to give relief and cure, but in panel work he must constantly ask himself: Is this a case of malingering? To show how grossly the system is exploited Dr. Liek quotes the following facts:—

> Of the 7,918,432 members of a group of insurance societies, 7,259,016 declared in one year that they were incapacitated through sickness and were invited to undergo re-examination after the granting of a sickness certificate by their panel doctors. No less than 198,142 immediately announced that they were well, and that no further examination was called for. A further 219,913 declared to the re-examining doctor that they had suddenly become quite well. Of the remaining number, 292,133 workers who had pretended to be incapacitated were found on re-examination to be able to work. In other words, out of the 1,259,016 nominally incapacitated, no less than 710,188, or 56·5 per cent., were quite able to work.

The sickness insurance organisations become mere dole payers as soon as a period of unemployment begins. "In a little town known to me," says Dr. Liek, "ten railway workers were dismissed on a certain day. Out of these ten men no less than nine were immediately certified as incapacitated by illness by their panel doctors. A friend of mine, a manufacturer, had to dismiss 50 women workers. During the next few days 49 of them received the certificate that they were incapacitated by illness which enabled them to draw sickness pay."

As at present organised sickness insurance "does shoddy work, is inefficient, and is at the same time expensive." In Danzig 7 per cent. and in Berlin 6 per cent. of the worker's income is expended on this alone. In 1927 the cost of the scheme worked out at £4 3*s*. per head (or including dependents £2 8*s*.). This amount is far too high. "I do not think that many uninsured civil servants and professional men are prepared to pay year by year 7 per cent. of their income to doctors and chemists." The expenditure on the huge bureaucratic organisation is gigantic. According to the *Ärztliche Mitteilungen* there are in Germany 29,403 insurance doctors to cure the insured sick, and no less than 27,000 officials in the employ of the insurance organisations. Moreover, the spirit of bureaucracy has invaded medical practice.

> "Having to attend impossibly large numbers, doctors become accustomed to doing rush work, and they lose the capacity and inclination to examine and treat their patients with conscientious care. After all, the question of curing the patient is less important than that of carrying out the regulations of the organisation which pays the doctor! A large number of insurance doctors consider it their principal duty to fill up forms for official use, keep books, &c."

If there were no social insurance free competition among medical men would lead automatically to

[1] The Doctor's Mission: Reflections, Reminiscences, and Revelations of a Medical Man. By Dr. Erwin Liek. Translated with an introduction by J. Ellis Barker. London: John Murray. 1930. Pp. 276. 6*s*.

success among the able and competent. But "the possibility of making a living by panel practice induces many to study medicine who do not feel the call to enter the profession. It has created medical profiteers and shopkeepers."

Dr. Liek does not believe that the general improvement of the national health is due to national sickness insurance. "Politicians and doctors," he says, "live under the illusion that they have brought about certain improvements for which, as a matter of fact, they are not responsible." He quotes Dr. Stappert as follows:—

"Every day the flood of men and women who clamour for sick-pay is rising. This flood beats ever more strongly against the wall of the medical profession, and doctors must spend their strength, energy, and ability to resist the flood. Otherwise they will be overwhelmed. The social insurance system is rotten to the core, and the edifice would have collapsed long ago, had it not been for the unselfishness and conscientiousness of the medical men."

Under such circumstances, Dr. Liek says, it is incomprehensible that the State continues enlarging the scope of social insurance from year to year. "I am sure that all the social insurance schemes were put forward with the best intention in the world, and they would have fulfilled their object if all men were animated by unselfishness, love of their neighbours, joy in their labour, love of truth, &c. As long as men remain men of the type we know, the selfishness of the individual will prevail over his higher sentiments and will nullify the aims of philanthropists and legislators who devised these schemes."

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS.

NURSES' WAGES AND HOURS.

IN the House of Commons on Dec. 10th Mr. BROCKWAY asked leave to bring in a Bill to lay down minimum wages and maximum working hours for the nursing profession. He said there was in the press at present a discussion as to the reason why the number of recruits to the nursing profession was falling. He suggested that one reason was the effect of the conditions under which the members of the profession were employed. In 1927 a very representative conference considered the question of medical organisations, hospitals, and approved societies, over which the present Minister of Pensions (Mr. Roberts) presided, and the opening address was delivered by the present Prime Minister. In that address Mr. MacDonald used these words: "Our object is to improve the conditions of the nurses. The work is onerous, and because they have given their services with such extraordinary devotion in the past no one has any right to assume that much need not be done to show our gratitude, not merely in words, but in a way that will materialise to their advantage." This Bill was an attempt to give effect to those words. In connexion with that conference a report was issued based on a questionaire which had been answered by 138 hospitals, poor-law infirmaries, district nursing associations, and he was assured by authoritative nursing organisations that the facts in the report were substantially accurate. It was on those facts that he based his case to-day. His Bill would apply to two categories in the nursing profession; in the first place, to the nurses employed by hospitals and in similar institutions, and, in the second place, to the large number of women employed as district nurses. The minimum wages and maximum hours which he proposed were those already in operation in the best hospitals and institutions, and therefore the proposals in the Bill were practicable. In some hospitals a 44-hour working week was in operation; in others, the week was one of 66 hours, an average of 11 hours. In cases where night duty was performed, the working week was sometimes one of 84 hours, or six shifts of 14 hours. But in many cases the 12-hour night duty was common. Of particular importance in this connexion were the probationers, who did a great deal of the work of the hospitals and were simultaneously students and had to prepare for examination. The Bill proposed that for all nurses there should be a minimum working week of 48 hours, except in cases of emergency, where the time should be made up at a later period. So far as wages were concerned, the maximum wage of £40 per year was now paid to some probationers, £75 to nurses, and £85 to sisters. His proposal was that those figures, already paid in the best hospitals, should become the minimum for all hospitals. Again, the need for legislation of this kind was illustrated by the fact that in some hospitals the salary for probationers was actually as low in the first year as £1 a month, or 4*s*. 8*d*. a week; in the second year £16; and, in the third year, £20. In some cases the nurses were only paid £30 a year after three years' training, and sisters were only paid £40 a year not only after three years' training but many years' service as nurses. He suggested that in those cases the rates for the probationers should be a minimum of £40 in the first year; £50 in the second; and £60 in the third. For nurses they should begin at £75, rising in the second year to £80. For sisters the rates should be £85, rising within five years to a minimum of £100. In the case of district nurses he suggested that the minimum rate should be £85, rising by £5 annually to £100, where board, lodging, laundry, and uniform were provided, and £185, rising by £5 annually to £200, where these were not provided. Nurses were performing a great service to the whole of the community. The least the community could do was to save them from working in a sweated profession.

Leave was granted, and the Bill was brought in amid general cheers.

UNEMPLOYED PERSONS AND HEALTH INSURANCE.

On Monday last in reply to a question whether those persons whose insurance lapsed at the end of the present year as a result of prolonged unemployment would be enabled to continue drawing benefit until legislation was passed, Mr. GREENWOOD (Minister of Health) referred to the terms of a financial resolution in connexion with the National Health Insurance (Prolongation of Insurance) Bill, which reads as follows:—

"That it is expedient (*a*) to amend the sub section substituted by the National Health Insurance Act, 1928 (hereinafter referred to as 'the Act of 1928'), for Subsection (3) of Section 3 of the National Health Insurance Act, 1924 (hereinafter referred to as 'the Act of 1924'), by providing that a person who has, under the said substituted subsection or under that subsection as applied by the regulations made under Section 23 of the Act of 1928, been treated as an employed contributor insured under the Act of 1924, shall continue to be so treated until Dec. 31st, 1931, if he satisfies the condition contained in paragraph (*a*) of the said subsection and also the following condition, that is to say, if he proves within the prescribed time that throughout the year immediately preceding the end of the period during which he was by virtue of the said substituted subsection treated as an employed contributor insured under the Act of 1924, he was at all times when not employed within the meaning of the Act of 1924, either available for but unable to obtain employment within the meaning of the Act of 1924, or incapable of working by reason of some specific disease or bodily or mental disablement of which notice was given within the prescribed time; (*b*) to authorise the payment out of moneys provided by Parliament—(i) of a

sum equal to 36 contributions (at the rate of 9*d.* in the case of a man and 8½*d.* in the case of a woman) in respect of every person to whom this resolution applies, such sum to be paid or credited to the fund or account out of which the benefits to which that person is entitled are defrayed; and (ii) of the additional cost of benefits under the Act of 1924, and the expenses of administration of those benefits (so far as such cost and expenses are payable out of moneys provided by Parliament) consequent on the provisions of paragraph (*a*) of this resolution."

Mr. GREENWOOD said an agreement had been arrived at which would enable the Bill to become law this week. The purpose of the money resolution was to retain in insurance a number of people who under the existing law and regulations would cease to be in insurance for health insurance and widows' and old age pensions at the end of this year. The Government desired to retain them in insurance at the expense of the Exchequer.

The resolution was agreed to.

SLAUGHTER OF ANIMALS BILL.

In the House of Commons on Friday, Dec. 12th, Lieut.-Colonel MOORE, in moving the second reading of the Slaughter of Animals Bill, said its object was to ensure that all animals slaughtered in slaughter-houses and knackers' yards in England, whether for human food or otherwise, should be humanely killed. It provided that all animals should be instantaneously killed or stunned by a mechanically operated instrument, and provided that all slaughtermen should be licensed so that only competent and reliable men should be engaged in the work. There were provisions for the proper inspection of slaughter-houses and knackers' yards, and it provided that Jews and Mahommedans should be permitted to slaughter animals in accordance with their religious beliefs. The Ministry of Health issued some years ago model by-laws for slaughter-houses providing for the use of mechanical instruments which might be adopted voluntarily by local authorities, and 930 local authorities had adopted those model by-laws which were incorporated in the Bill and applied to the whole country. He had been overwhelmed with letters from all sections of the community expressing surprise that the humane slaughter of animals was not universal, and encouraging him in his efforts to make it so. Every year between 14,000,000 and 16,000,000 animals were killed for human food. The great advantage of the mechanical killer was that it had a captive bolt which was released by the pressure of the cartridge and penetrated the brain of the animal. The type and length of the bolt depended on the type of animal to be slaughtered. There was little strength needed; no skill, but merely ordinary care. The carcass of the animal was undamaged, and the cost was inappreciable. Thousands of practising butchers had voluntarily adopted the system. The Bill exempted Jews and Mahommedans as the promoters did not think it wise to interfere with the fundamental religious views of any race.

Lieut.-Commander KENWORTHY seconded the motion for the second reading.

A BLOCKING AMENDMENT.

Mr. LANG moved "that this House declines to give a second reading to the Bill until the whole subject of the slaughter of animals has been fully investigated by a Select Committee of this House." He said that either the Jewish method of killing animals was humane or it was not—if it was not it was a very serious thing to give exemption under this Bill to one religious community. He was not at all satisfied that the case for the Bill had been made out. When there was a striking difference of opinion among eminent scientific people who had no axes to grind in the matter he thought that the proper course was to subject the matter to further investigation by a Select Committee.

Mr. BLINDELL seconded the amendment.

Mr. GREENWOOD (Minister of Health) said that a substantial and growing number of local authorities had adopted humane slaughter. There was also a change in the attitude of those who represented the meat trade. He warned the promoters, however, that if the Bill got a second reading they would be only at the beginning of their troubles. He suggested that they should set about arriving at an agreed basis which would render the Bill more or less non-controversial.

"THE ABSOLUTE MINIMUM."

After further debate,

Sir R. GOWER said that before the Bill had been presented to the House careful consideration was given by its promoters to all its provisions, and it was felt that those provisions represented the absolute minimum. He was profoundly disappointed at the statement of the Minister of Health, and he appealed once more strongly to the Government to give the necessary facilities for the passage of the Bill. The promoters were prepared to face every difficulty, and if it appeared that they could not get the whole of the Bill they would consider any suggestions which might be made. A short time ago it was stated in THE LANCET that the medical officer of health of Bloemfontein in South Africa reported that many thousands of pigs had been slaughtered by the humane killer, and in no case had there been any complaints as to insufficient bleeding or the keeping quality of the meat. Not very long ago, too, the medical officer for health for Brighton stated in his report that a large number of pigs were slaughtered there by means of the humane killer, and that there was very little evidence of blood-splashing.

MEDICAL SUPPORT TO THE BILL.

Dr. HASTINGS said the physiology of human beings was very similar to the larger animals used for food. Members of the medical profession learned a very long time ago that when they wished to do anything unpleasant to any of their victims it paid them well to render them anæsthetic, and that was the great point in this Bill. Many of the speakers in that discussion had omitted to take account of the fact that the whole question was one of rendering the animal unconscious as quickly as possible. What did it matter how long the animal bled if it was unconscious? He was quite sure that it was much easier to hold a pistol to an animal's head than to wield a weapon which very much resembled a pickaxe, and strike with it an exact point on the skull. Another question which had been discussed was that of blood-splashing. He did not think there was any doubt from the facts that had been brought forward that day that blood-splashing did occur in carcasses killed by all methods; but he suggested that the cause of blood-splashing was mainly fear. They knew very well physiologically that fear had the effect of letting into the blood stream the secretion of the adrenal gland, and one of the effects of this was to raise the blood tension and therefore make bleeding occur more easily. Sufficient stress had not been laid on the importance of licensing those who had to slaughter animals. It was not an easy thing to slaughter an animal, particularly with the knife. Only those who were really skilled should undertake these operations. He would support the Bill.

Dr. LITTLE said he wished to emphasise the point that there was more bungling likely to occur in killing an animal with the poleaxe than with the humane killer, especially if it were in expert hands, and if they could reduce the amount of suffering which was caused by bungling it was their duty to do so. He would emphasise the point made by the Minister of Health as regarded the importance of public feeling in a matter of this kind. In the case of experiments on animals most careful regulations were insisted upon to prevent pain and suffering. The President of the College of Physicians, or the College of Surgeons, if they desired to make an experiment on an animal, were obliged to take, and

quite rightly, the very strictest measures to avoid pain. This method of killing had been demonstrated to be the quickest way of achieving unconsciousness. One of the most eminent physiologists of this generation pointed out that the animal became unconscious before the impact of the blow could be properly effected. That was a statement which should have great weight indeed, as it made it obvious that this was the method which ought to be chosen. In this matter they must take into consideration public opinion and remove a reproach which was a serious blot on the country at the moment.

Lieut.-Colonel FREMANTLE said there was something left to be said on this Bill from the point of view of the professional man who had had to look into the question as a medical officer of health. He had seen the big slaughter-houses in Paris and in various parts of Germany, and had noted the contrast between those big abattoirs, where everything was done so well, and the slaughter-houses in this country. It was for that reason among others that he welcomed this Bill as a step in the direction which they had been keen on taking for so many years. By sending the Bill to a standing committee they were not prejudicing the case of the bacon-curers, but by sending the Bill to a Select Committee they would tie up the case interminably against the general feeling of the House, and he believed the general feeling of the health profession, scientific men, and humane people.

AMENDMENT WITHDRAWN.

Mr. LANG said in view of the statements they had heard that afternoon from the Minister of Health and others, that only an agreed measure was likely to reach the Statute Book, he would not press the matter to a division, but would withdraw his amendment in the hope that such measure of agreement might be arrived at.

The Bill was read a second time and committed to a Standing Committee.

HOUSE OF COMMONS.

WEDNESDAY, DEC. 10TH.

Tuberculosis in the Navy.

Viscountess ASTOR asked the First Lord of the Admiralty the number of cases of tuberculosis in the Royal Navy as a whole for each year in the last ten years.—Mr. G. H. HALL replied: The numbers of cases of tuberculosis, pulmonary and non-pulmonary, in the Royal Navy as a whole for each year in the last nine years were as follows: 1921, 284; 1922, 224; 1923, 173; 1924, 204; 1925, 262; 1926, 222; 1927, 193; 1928, 188; 1929, 272. I regret that the figures for ten years are not available.

Poisoning of Sweets.

Mr. FREEMAN asked the Minister of Health whether his attention had been called to a number of recent cases of the poisoning of sweets, notably by arsenic; and whether he intended holding any inquiry into the matter.—Miss LAWRENCE replied: My right hon. friend is aware of the cases referred to, and he understands that the local authority concerned has taken suitable action, including the prosecution of the persons responsible. Officers of my department have kept in close touch with those of the local authority in the course of the investigations, and my right hon. friend does not think it necessary to hold any special inquiry into the matter. I may add that my right hon. friend is in consultation with the Secretary of State on the question of legislation to guard against the danger of the accidental misuse of poisons.

THURSDAY, DEC. 11TH.

Law of Sweepstakes and Lotteries.

Mr. DAY asked the Home Secretary whether, in view of the present condition of the law on the subject of sweepstakes, lotteries, and raffles, he would consider the appointment of a committee for the purpose of recommending legislation with a view to clarifying the position.—Mr. CLYNES replied: Under the existing law, public lotteries of whatever form and whether promoted in this country or not are illegal in this country, and while that is the case the authorities have no alternative but to carry out the law. Under the Customs Acts, advertisements or notices of lotteries are contraband, and upon importation, by whatever means, can be dealt with accordingly. The sending of lottery tickets or advertisements through the post is also prohibited, and letters suspected of containing correspondence relating to lotteries may be opened. The Statute provides heavy penalties for breaches of the law. If I were satisfied of the existence of any general demand that I should look into the question of setting up a committee to consider, as a practical question, the conditions and safeguards which would be necessary and appropriate if lotteries were to be permitted as a method of raising money for approved public purposes, I should be prepared to consider what would be the best method of giving effect to such a demand.

The Sale of Arsenic.

Sir GEORGE PENNY asked the Home Secretary whether, in view of the opinion expressed by coroners, he would consider a revision of the regulations controlling the sale of arsenic to the public so that, if this poison was indispensable to agriculture, the licensed vendors, such as corn merchants, ironmongers, &c., would be made to comply with the same regulations as registered chemists.—Mr. CLYNES replied: I hope that a Bill for the purpose of simplifying and strengthening the law relating to poisons may shortly be introduced into Parliament. I would, however, remind the hon. Member that the existing provisions of the law relating to the sale of arsenic and of poisons generally apply equally to registered chemists and the licensed vendors to whom he refers. The licensed vendors are, in addition, subject to the regulations made by Order in Council under Section 2 of the Poisons and Pharmacy Act, 1908.

Medical Examination of School-children.

Dr. HASTINGS asked the President of the Board of Education the approximate time per capita taken in the medical examination of school-children.—Sir CHARLES TREVELYAN replied: When children are being examined at routine medical inspections, about six minutes is occupied on the average in the inspection of each child. Children discovered or suspected to be suffering from defects requiring more detailed investigation are referred for subsequent examination, and the time then given to any particular child, of course, varies with the nature of the defect.

Epidemic in the Meuse Valley.

Colonel HOWARD-BURY asked the Minister of Health whether, in view of the fact that 65 deaths had been caused in Belgium by sulphuric acid fumes and fog, he was taking steps to see that a similar result did not happen from a combination of fog and sulphuric acid fumes from the Battersea power station being erected in the heart of London.—Mr. GREENWOOD replied: The Belgian Ministry of the Interior have instituted an official inquiry into this matter, and I have asked to be favoured with a copy of the report. Until the facts are ascertained, I know no grounds for assuming that sulphuric acid or any other fumes are associated with the cause of the outbreak, but, as regards the Battersea power station, I would draw attention to the report presented to Parliament last month by the Minister of Transport in which it is stated that the committee presided over by the Government chemist are satisfied that it is practicable to instal there a plant which will reduce the emission of sulphur fumes to a negligible quantity.

MONDAY, DEC. 15TH.

Male Nurses in Mental Institutions.

Mr. DAY asked the Minister of Pensions the number of the male nursing staff employed in the institutions under his control dealing in cases of mental and severe nervous disorder who had not the qualifications of a certificate for dealing with such cases.—Mr. J. A. PARKINSON (Lord of the Treasury) replied: There are some 165 orderlies employed in the institutions under the control of the Department which provide treatment for mental and severe nervous affections. Of these 33 are in possession of a certificate. The bulk of the remainder have, however, had ten years' experience and upwards in mental institutions. It may be pointed out that a majority of the patients in the institutions referred to are not certified cases.

English Tests of Spahlinger Vaccine.

Mr. HURD asked the Minister of Agriculture whether his attention had been called to the tests by an expert and impartial committee in Norfolk of the Spahlinger vaccine as a preventive against bovine tuberculosis; and whether his department was making further inquiries.—Dr. ADDISON replied: Captain Richard Buxton has been good enough to present me with a summary of the report of the interesting experiments with M. Spahlinger's vaccine which have been carried out on his farm in Norfolk. I have suggested to him, in the interest of all concerned in the problem, that he should arrange for a complete test to be made by and under the

independent control of recognised authorities who are experienced in research in this disease.

War Pensioners' Claims.

Brigadier-General MAKINS asked the Minister of Pensions the total number of claims submitted outside the seven years' limit up to Nov. 30th, 1930, since his announcement in regard to this matter in November, 1929; how many of these applications had been considered and dealt with; and how many of them had received favourable consideration.—Mr. PARKINSON replied: Some 20,300 fresh claims have been submitted during the period referred to, of which rather more than 18,000 have been considered. In 982 cases the claims have been recognised either by way of medical or surgical treatment, or by some form of pecuniary compensation.

Independent Medical Authority and Pension Claims.

Mr. STEPHEN asked the Minister of Pensions in how many disputed cases there had been reference to an independent medical authority, in accordance with the new arrangements made since he took office.—Mr. PARKINSON replied: The number of such cases up to the end of last month was 251.

Advertisements of Hall's Wine.

Dr. HASTINGS asked the Postmaster-General whether his attention had been called to the fact that advertisements for Hall's wine were contained in books of stamps sold at post offices; whether, in view of the fact that this wine contained a large percentage of alcohol and could only be retailed by those holding a licence, and that it was without medicinal value because the small quantity of meat juice that it contained was rendered inert by the action of the alcohol in it, he would take steps to see that such advertisements were no longer accepted.—Mr. LEES-SMITH replied: In accordance with the Government's general decision, no advertisement of alcoholic liquor is now accepted for inclusion in post office books of stamps; and this decision applies to advertisements of Hall's wine. Any such advertisements appearing in stamp books now on sale represent issues printed before the decision took effect.

Shell Shock and War Neurasthenia.

Mr. PRICE asked the Minister of Pensions how many persons suffering from shell shock and war neurasthenia were in receipt of pensions at the present time; and whether, in view of the ill-effect on general health of worry on the minds of these persons as to the certainty of their pensions continuing, he would consider making these pensions permanent.—Mr. ROBERTS replied: The total number of officers and men at present in receipt of pension on account of neurasthenia is about 32,000. It is the policy of the Ministry to make final awards in all suitable cases, and, as a matter of fact, in 28,000 of the total number of cases referred to the awards have been made permanent.

War Pensioners and Attributability.

Dr. MORRIS-JONES asked the Minister of Pensions if he was aware that in certain cases pensioners who had been given the entitlement of attributability for their pensionable conditions were dealt with on an aggravation basis, although notified as attributable, and were thus deprived of their right of appeal to the pensions appeal tribunal on entitlement; and whether he would inquire into the matter.—Mr. ROBERTS replied: In no case is any change of entitlement affecting pension made, which could form the subject of appeal, without such right of appeal being given.

TUESDAY, DEC. 16TH.

Vivisection Experiments.

Lieut.-Commander KENWORTHY asked leave to introduce a Bill to prevent the application of public money to vivisection experiments.

Major CHURCH opposed the Bill.

Leave to introduce the Bill was refused by 170 votes to 156—majority against, 14.

Scottish Prisoners and Insanity.

Mr. STEPHEN asked the Secretary for Scotland whether he proposed to take any steps to deal with the position of persons charged with an offence, but incapable of pleading through insanity, who had afterwards recovered and been sane for years.—Mr. ADAMSON replied: According to existing practice the cases of individual inmates of the Criminal Lunatic Department are considered periodically. In consultation with my right hon. friend, the Lord Advocate, I am examining the existing procedure with a view to ascertaining whether any modification of it is desirable.

Mortality and Sickness among Seamen.

Mr. THOMAS LEWIS asked the President of the Board of Trade whether, in view of the mortality and sickness experienced amongst seamen, he intended, at an early date, to take steps to secure an improvement in the accommodation provided for the crews of the mercantile marine.—Mr. W. GRAHAM replied: An investigation is being made to determine what are the true death- and sickness-rates amongst seamen as compared with other occupations. The accommodation on board ship, which is frequently inspected by the surveyors of the Board of Trade and by the local health authorities, has recently been engaging the special attention of the Board of Trade, of the Joint Committee of the Board of Trade and Ministry of Health, and of the Shipping Federation. I hope that agreed proposals improving the general standard of crew accommodation will result from these inquiries.

Radium Supplies.

Commander BELLAIRS asked the Minister of Health, in view of the undertaking of the last Government to refer the question of radium supplies and prices to the League of Nations, what progress had been achieved; and whether the League had inquired into both the prices and supplies from the Union Minière in Belgian territory.—Mr. GREENWOOD replied: I am not aware that any undertaking such as is suggested by the hon. and gallant Member was given, but I am informed that proposals for investigation of these matters were made at the last session of the Health Committee of the League of Nations, and will be further considered at the next meeting of that Committee.

MEDICAL NEWS

Royal College of Surgeons of England.

A meeting of the Council of the College was held on Dec. 11th, with Lord Moynihan, the President, in the chair.

Mr. Russell Howard (Surgeon to the London Hospital) was re-elected, and Mr. E. C. Hughes (Assistant Surgeon to Guy's Hospital) and Mr. L. E. C. Norbury (Surgeon to the Royal Free Hospital) were elected Members of the Court of Examiners.

Diplomas of Membership were granted to Marjorie Low Royal Free); Marjorie N. Lunn (Royal Free); E. Mary Newham (Royal Free); and David Ockman (Manchester).

The Fellowship of the College was conferred on the ollowing:—

Gladys Maud Sandes, Royal Free; John Maxwell Clarke,)tago and St. Bart.'s; Walter Graham Scott Brown, St. Bart.'s; annie Pichaimuthu, Madras; James Harold Saint, Durham and ondon; Reginald Cyril Tatham, Middlesex; Norman William olton, Manchester; James Cecil Hogg, Cambridge and St. art.'s; Walter Stanley Chapman, Univ. Coll.; Ralph Marnham, ambridge and St. George's; Basil Roy Sworn and Richard lood Metcalfe, St. Thomas's; Derek Gordon Bown, Guy's; rederick Herman Aitken Walker, Cambridge and St. Bart.'s; bdulla Ali, Cairo and London; Prem Nihar Ray, Calcutta nd St. Bart.'s; Robin Sturtevant Pilcher, Univ. Coll.; Wilfred ynes, Leeds and St. Bart.'s; Judson Tynedale Chesterman, ristol and Guy's; Max Roslyn Ernst, St. Bart.'s; Eric Newton ardle, Liverpool and London; Hussein Yousri, Birmingham and King's Coll.; Motibhai Desaibhai Patel, Guy's and London; John Roydon Peacock, Cambridge and St. George's; Philip Joseph Ganner, Birmingham and London; Norman Rupert Barrett, St. Thomas's; Alfred Charles Fisher, Bristol and Guy's; William Eldon Tucker, Cambridge and St. George's; Harold Strang Taylor-Young, Cambridge and St. Thomas's; Cecil Edwin Corrigan, Manitoba and St. Bart.'s; Alan Doyle Everett, St. Bart.'s; Frank Wild Holdsworth, Cambridge and St. George's; Raymond Purvis, St. Thomas's; Terence John Millin, Dublin and Guy's; Frederick Ross Stansfield, Leeds and St. Bart.'s; Francis Florence D'Arcy, Melbourne and Guy's; Sydney Gordon Davidson, Aberdeen and Guy's; David Imrie Fitzpatrick, Melbourne and Guy's; Edward Charles Bell Jones, Melbourne and London; James Fong Kemble, Sydney, Guy's and St. Bart.'s; Kenneth Lumsden, Edinburgh and St. Bart.'s; Edward Gerard MacMahon and Norman St. Clair Mulhearn, Sydney and Guy's; Lloyd Reath Olver, Sydney and St. Bart.'s; Kenneth Charles Trineman Rawle, Sydney and Guy's; Cecil Ashley Marshal Renou, Melbourne; Vithal Nagesh Shirodkar, Bombay and Guy's; George Robin Adlington Syme, Melbourne and Guy's; Jacob Taliat, Bombay and London; and Samuel Aird McCleery Thompson, Belfast and London.

Three other candidates were successful in the recent examination, but have not yet complied with the regulations—namely, Alfred Richard Denis Pattison, Kenneth Hampden Pridie, and Israel Preiskel.

The Licence in Dental Surgery was granted to Pondichery Somasunder, M.R.C.S. (Madras and London).

At the request of the Canadian Medical Association it was

decided to hold a primary examination for the Fellowship in Canada in 1931.

At the primary examination for the Fellowship, held from Dec. 2nd to 13th, 178 candidates presented themselves, of whom 57 were approved. The following are the names and medical schools of the successful candidates:—

S. C. Alagappan, M.B., Madras Univ. and Middlesex; A. V. Baliga, L.C.P.S., Bombay, King's Coll., and Middlesex; F. H. Bentley, M.B., Manchester; A. Birnbaum, London; G. W. Black, M.B., Middlesex; H. A. Body, M.D., Melbourne and Middlesex; S. G. Browne, King's Coll.; M. Bryer, M.R.C.S., St. Bart.'s and Middlesex; E. L. Button, M.B., Otago and St. Mary's; E. G. L. Bywaters, Middlesex; F. A. d'Abreu, M.B., Birmingham, St. Mary's, and Middlesex; D. O. Davies, St. Bart.'s; G. Y. Feggetter, M.B., Durham; S. Y. Feggetter, Durham; G. S. Ferraby, M.B., King's Coll. and St. Mary's; W. C. Gissane, M.B., Sydney Univ.; J. Grocott, Guy's; J. D. Hay, Cambridge; F. J. Hector, M.R.C.S., Bristol and Middlesex; J. C. R. Hindenach, M.B., Otago and Middlesex; F. K. S. Hirschfeld, M.R.C.S., Melbourne, Oxford, and London; Eva Ho-Tung, M.B., Hong-Kong and King's Coll.; W. E. A. Hughes-Jones, M.B., Melbourne Univ.; Muriel S. Hulke, M.B., Univ. Coll.; E. A. Hunt, M.B., Toronto Univ.; J. Kelley, M.B., Cork; H. B. Lee, St. Bart.'s; G. J. Lillie, M.B., Melbourne and King's Coll.; E. W. Lindeck, M.B., Camb. and Univ. Coll.; W. S. McKenzie, Camb. and Middlesex; R. J. W. Malcolm, M.B., Sydney and Middlesex; G. S. Malik, M.B., Univ. Coll.; B. R. Medlycott, M.B., Guy's; T. W. Mimpriss, M.R.C.S., St. Thomas's; W. F. Nicholson, Camb. and Middlesex; J. A. R. O'Regan, M.B., Otago Univ.; R. C. Percival, Sydney and London; K. M. A. Perry, Camb. and London; H. A. Phillips, M.D., Melbourne and Middlesex; A. K. Price, St. Thomas's; R. B. Pringle, M.R.C.S., Camb. and St. Thomas's; R. W. Raven, M.R.C.S., St. Bart.'s; R. K. Reeves, M.B., Adelaide and London; L. C. Rogers, M.R.C.S., Middlesex; L. S. Rogers, M.B., Otago and St. Mary's; G. F. Rowbotham, M.R.C.S., Manchester and Middlesex; B. W. Rycroft, M.D., St. Andrews and Middlesex; R. Shackman, St. Bart.'s; M. Silverstone, M.B., Liverpool Univ.; C. G. Sinclair, M.B., St. Bart.'s.; V. A. J. Swain, St. Bart.'s; S. M. Thompson, Camb. and King's Coll.; T. M. Tyrrell, Camb. and St. Thomas's; F. Welsh, M.B., Birmingham Univ.; W. K. Welsh, Toronto Univ.; I. G. Williams, Middlesex; and H. R. I. Wolfe, St. Thomas's.

University of London.

At recent examinations the following candidates were successful:—

THIRD EXAMINATION FOR M.B., B.S.

Honours.—M. P. Ellis (*a*), Univ. Coll. Hosp.; R. A. Fitzsimons (*d*), Charing Cross Hosp.; Beatrice M. Joly (*a*), L.S.M.W.; G. L. Jones (*c*), St. Thomas's Hosp.; Michael Kremer (*a*), Middlesex Hosp.; D. W. C. Northfield (*d, e, University Medal*), Guy's Hosp.; and A. W. M. Rooke, Univ. Coll. Hosp.

(*a*) Distinguished in Medicine. (*d*) Distinguished in Surgery.
(*c*) Distinguished in Forensic Medicine.
(*e*) Distinguished in Midwifery.

Pass.—E. F. Barnardo, London Hosp.; F. G. L. Barnes St. Bart.'s Hosp.; Jamshed Nusserwanji Bhada, Univ. Coll. Hosp.; W. L. M. Bigby, Guy's Hosp.; J. G. Bowen, London Hosp.; W. E. R. Branch, Univ. Coll. Hosp.; Dora E. Brockbank, L.S.M.W.; F. E. Camps, Guy's Hosp.; W. H. P. Cant, Univ. of Birmingham; A. G. Carmichael, Middlesex Hosp.; Rosa E. Chamings, L.S.M.W.; Arnold Clark and E. E. Claxton, St. Bart.'s Hosp.; F. S. Cliff, Univ. Coll. Hosp.; W. D. Coltart, St. Bart.'s Hosp.; T. V. Cooper, Westminster Hosp.; Catherine B. Crane, L.S.M.W.; H. J. Croot, Guy's Hosp.; Marian J. Cunning and Catherine Day, L.S.M.W.; C. E. Dolman, St. Mary's Hosp.; D. G. Evans, Univ. Coll., Cardiff, and Univ. Coll. Hosp.; J. D. S. Flew, Univ. Coll. Hosp.; Beryl M. Furlong, Kamala Ghosh, Olive N. Grant, and Mary W. Hamlyn, L.S.M.W.; Flora Hargreaves, Univ. Coll. Hosp.; Lettice P. Harrison, L.S.M.W.; K. W. D. Hartley, St. Bart.'s Hosp.; Honor E. C. Harvey, L.S.M.W.; A. S. Hatch and Katherine M. Heberlet, Univ. Coll. Hosp.; P. Y. Hicks, St. Thomas's Hosp.; R. E. Holmes, London Hosp.; E. B. Jackson, Univ. Coll. Hosp.; H. B. Jackson, Middlesex Hosp.; E. K. Jones, London Hosp.; J. L. F. King and G. C. Knight, St. Barts.' Hosp.; H. J. Knight, St. Mary's Hosp.; Nellie I. Lanckenau and L. J. M. Laurent, Univ. Coll. Hosp.; I. W. Lazarus, London Hosp.; Arthur Levy, St. Thomas's Hosp; Annie M. McGrath, Westminster Hosp.; Joyce MacInnes, L.S.M.W.; A. H. MacG. McMullan, Univ. of Birmingham; Moyra I. Macnaughton-Jones, L.S.M.W.; Eileen M. Massey, King's Coll. Hosp.; Elizabeth T. Mess, L.S.M.W.; J. R. Murray, London Hosp.; A. M. Nussbrecher, Middlesex Hosp.; R. A. C. Rice, R. S. Risk, and A. H. T. Robb-Smith, St. Bart.'s Hosp.; C. P. Scott, St. Thomas's Hosp.; Violet R. Sharp and Dorothy A. Sharpe, L.S.M.W.; N. L. Shepperd, King's Coll. Hosp.; Everell M. Shippam, L.S.M.W.; C. K. Simpson, Guy's Hosp.; Effie Slater, Univ. of Leeds; Douglas Stanley-Jones, St. Bart.'s Hosp.; H. H. Steadman and F. H. Stevenson, Guy's Hosp.; T. S. Stone, London Hosp.; E. G. Thomas, Univ. Coll., Cardiff, and Univ. Coll. Hosp.; C. J. L. Thurgar, Univ. Coll. Hosp.; E. S. Vergette, St. Bart.'s Hosp.; J. C. S. Wells and A. S. Wigfield, Univ. Coll. Hosp.; E. R. Williams, St. Mary's Hosp.; Maureen D. Willmott Evans, L.S.M.W.; and T. H. Wilson, St. Thomas's Hosp.

L.S.M.W. = London School of Medicine for Women.

University of Manchester.

At recent examinations the following candidates were successful:—

FINAL EXAMINATION FOR M.B. AND CH.B.

A. N. Birkett, B. R. Bramwell, S. T. Cowan, C. G. Eastwood, J. R. P. Edkins, Dorothy A. Geiler, E. W. Hardman, Leslie Jones David Ockman, H. J. O'Loughlin, B. P. Robinson, and G. H. C. Walmsley.

Part I. (*Forensic Medicine, &c.*)—C. B. Ainscow, G. H. M. Franklin, J. K. Hadfield, J. F. E. Johnson, and E. D. Portman.

DIPLOMA IN DENTISTRY.

Edward Entwisle, J. B. Hoyles, Lawrence Moran, and Minnie H. Platford.

Royal Institution.

The Royal Institution has received an intimation from the Pilgrim Trust that under the terms of the gift of £2,000,000 to Great Britain by Mr. Edward S. Harkness, the trustees have allocated £16,000 to meet the deficiency on the fund for the reconstruction of the Institution.

The 105th course of Christmas lectures "adapted to a juvenile auditory" will be given by Prof. A. M. Tyndall at 3 P.M. on Dec. 30th and Jan. 1st, 3rd, 6th, 8th, and 10th. His subject will be the Electric Spark, and tickets (one guinea; juveniles, 10–16, half-price) are obtainable at the Institution, 21, Albemarle-street, London, W.1.

Appointments at the Ministry of Health.

The Minister of Health has appointed Sir Ernest Strohmenger to be Deputy Secretary to the Ministry of Health, in succession to Mr. E. R. Forber, and Mr. S. H. G. Hughes to be Principal Assistant Secretary for Finance and Accountant-General of the Ministry.

Lectures on Tropical Hygiene.

A series of eight lectures and demonstrations on tropical hygiene, which are intended for men and women outside the medical profession proceeding to the tropics, will be given at the London School of Hygiene and Tropical Medicine, by Lieut.-Colonel G. E. F. Stammers, from Jan. 14th to 23rd, at 2 P.M. A second series of lectures will be given from March 18th to 27th at 5 o'clock. Syllabuses and full particulars may be had from the Secretary of the School, Keppel-street, W.C. 1.

Voluntary Health and Pensions Insurance.

Dec. 31st is the latest date for taking up voluntary health insurance in the case of certain persons in "excepted employment." Those affected are railway clerks, municipal employees, and others, who have been paying contributions compulsorily for pensions (but not health insurance) since Jan. 2nd, 1930, or earlier, and who are given an opportunity by the Pensions Act of 1929 of becoming voluntary contributors for health insurance benefits as well as for pensions. Any person in this class who wishes to take advantage of the opportunity offered should therefore write at once to an approved society or to the Ministry of Health, Whitehall, London, S.W.

Research Fellowships in Tuberculosis.

The Medical Research Council announce that they have awarded three Dorothy Temple Cross Research Fellowships for 1930–31 to Arthur Ivan Granville McLaughlin, M.B., late Chief Assistant in the Tuberculosis Department of St. Thomas's Hospital; Reginald John Matthews, M.D., Chief Tuberculosis Officer of the Mid-Glamorgan area and Medical Superintendent of Cymla Hospital; and Lieut. Sidney Malcolm Burrows, R.A.M.C., attached to the Sudan Defence Force. Dr. McLaughlin has received a Fellowship for the study of methods of diagnosis and treatment at some chosen centre in the United States. Dr. Matthews and Lieutenant Burrows have received Senior Fellowships, and will make special studies of problems of tuberculosis among the native populations in Zanzibar and in the Bahr-el-Ghazal province of the Sudan, under arrangements made by the Council with the respective Governments. These are the first appointments to be made under the terms of the Dorothy Temple Cross benefaction.

Medico-Legal Society.

The annual dinner of this society was held on Dec. 12th at the Holborn Restaurant. The chair was taken by Earl Russell, past president, in the absence of the president, Lord Riddell, through illness. The toast of "Medicine and Law" was proposed by Sir William Willcox, who said that the two professions had much in common, both demanding great self-sacrifice and being very jealous mistresses. Medicine, however, was an ever-changing profession, depending on scientific knowledge, while law moved slowly and depended largely on precedent. Doctors and laymen were apt to be puzzled by the lawyer's behaviour as an advocate, and doctors were simple and honest people who could be turned inside out in the witness-box. Dr. R. A. Young, replying, welcomed the opportunity of addressing lawyers without the risk of that awful form of vivisection—cross-examination. Recently both law and medicine had been accused by the headmaster of Harrow of being accurate

professions; this was certainly a libel on medicine, for no biological study could be accurate. À propos of a lady who had said to him, "It is no fun being married to a doctor; you have neither a doctor nor a husband," he told the story of the famous physician who had warned his students of the dangers of antipyretic drugs by describing how his wife had once taken an overdose, and how he had returned home to find her collapsed, blue, clammy, and almost pulseless. Unfortunately, an inquisitive student had one day asked: "What steps did you take, sir?" "Steps?" the physician had replied, "I took no steps; she was not my patient." There were three things, Dr. Young concluded, on which medicine and law would never agree: the signs of intoxication, the criteria of insanity, and the demand of the doctors for professional privilege. Sir Thomas Hughes, replying for the law, protested that members of the Bar were the gentlest creatures in the world. Referring to Mr. Justice McCardie's recent remarks on perjury, he said that the learned judge was somewhat given to exaggeration, and his view must be accepted with caution. Making allowances for the great temptation to a prisoner giving evidence on his own behalf, perjury was not such a serious matter as Sir Henry McCardie had alleged. Mr. E. H. Tindal Atkinson, proposing the health of the society, described his experiences as a referee under the National Health Insurance Act, which had led him into some curious by-ways. He had learned that Richter's hernia had nothing to do with the great conductor, and that parkinsonian signs were not so agricultural as they sounded. He deplored the Latin and Greek phraseology which obscured medical reports; he had a feeling that the word "cæcal" had something to do with "hiding," and when he encountered it in a report he always wondered whether the writer really was concealing something. Witnesses were always ready with a theory of who was to blame, and he turned with relief to the medical reports, where he found fact and absolute impartiality. While doctors in this country continued to give evidence in this way there was little likelihood of a jury returning a verdict like that of the Irish tribunal which had said that the deceased had undoubtedly committed suicide, but added as a rider that they thought his end had been hastened by the post-mortem examination. Earl Russell, replying, said that the membership of the society had now passed 400. He did not think law and medicine had very much in common, but they both sought the truth. The desire of the doctor to tell the exact and simple truth was sometimes what made him so annoying to the lawyer who called him as a witness. Contesting Sir William Willcox's suggestion that law had ossified in its shell, he cited the many recent revolutionary Acts of Parliament passed by lawyers, particularly the Property Acts of 1925. Sir Albion Richardson proposed "The Guests," and Sir Alfred Tobin and Lieut.-Colonel C. T. Samman replied.

The Old Epsomian Club.

The annual dinner of the Old Epsomian Club was held at the Hotel Great Central, London, on Thursday, Dec. 11th, when Dr. L. L. C. Reynolds presided over a large company of members and guests. After the loyal toasts, the health of the president was proposed by Mr. A. C. C. Parkinson, who commented upon Dr. Reynolds's fine record at Epsom, when, he said, the early interest which he took in the school rifle corps foreshadowed the admirable record which he secured in the Great War; for he was mentioned in despatches five times, decorated by the French and Italian Governments, and obtained also the D.S.O. with bar. Dr. Reynolds in his reply took up none of the allusions to his military career, but briefly stated how he viewed the development of the school since his boyhood, with its material extensions and the accumulation of a valuable tradition. He was here speaking to the second toast "Floreat Epsomia," of which he was the proposer, when the headmaster, Mr. A. C. Powell, responded by telling, with details, the creditable performances of the school during the past year in classroom and playing field. He made particular allusion to the construction of the new sanatorium, now in the building, and designed to be a model of what a public school sanatorium should be. The toast of the Guests was proposed by Mr. George Neligan, who coupled with it the names of Viscount Burnham (the President of the College) and Lord Dawson of Penn. Lord Burnham declared his gratification in succeeding to the office of President such men as Lord Granville and Lord Rosebery, the latter of whom was a dear friend of his own. Lord Dawson, who began in light vein with several amusing stories, went on to address members of the medical profession present, warning them to be ready for social developments which were bound to ensue, and which would lead to situations when doctors would find it not only necessary but their duty to get into far closer relations with the public. The dinner was felt by all present to have been an enjoyable one.

Appointments

BAILEY, H., F.R.C.S. Eng., has been appointed Surgeon, Royal Northern Hospital, London.

LAMONT, D. C., M.B., Ch.B. Edin., D.P.H., Medical Officer of Health for Burnley.

MULCAHY, AILEEN M., L.R.C.P.I., L.R.C.S.I., D.P.H., Temporary Asst. Medical Officer of Health, Galway.

Certifying Surgeons under the Factory and Workshop Acts: HAY, W. K., M.B., B.Ch. Belf. (Market Drayton); RITCHIE, H. N. (Hoyland Nether, West Riding).

Vacancies

For further information refer to the advertisement columns.

Aberdeen Royal Infirmary.—Asst. Surg. to Dental Department.
Accrington Victoria Hospital.—H.S. £150.
Birmingham General Hospital.—Two Res. Surg. Registrars. Each £100. Res. Anæsthetist. £120. Also H.P., and Two H.S.'s. Each £70.
Bradford Royal Infirmary.—Hon. Surg. Also Hon. Asst. Surg.
Brighton, Royal Sussex County Hospital.—Cas. H.S. £120.
Bristol General Hospital.—H.P.'s, H.S.'s, Res. Obstet. O. Each at rate of £80. Also Cas. H.S. At rate of £100.
Bristol, Hortham Colony for Mental Defectives.—Med. Supt. £700.
Burnley, Victoria Hospital.—Two H.S.'s. Each at rate of £150.
Bury St. Edmunds, West Suffolk General Hospital.—Jun. Res. M.O. £150.
Cardiff Royal Infirmary.—Two Hon. Asst. Surgeons.
Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.—Sen. and Jun. H.S. £120 and £100 respectively.
Chesterfield and North Derbyshire Royal Hospital.—H.S.'s. All at rate of £100–£175.
Derby County Mental Hospital, Mickleover.—Jun. Asst. M.O. £350.
Durham County Hospital.—Two H.S.'s. Each £150.
Hertford County Hospital.—Hon. Asst. Surg. Also H.P. At rate of £150.
Hospital of St. John and St. Elizabeth, 60, Grove End-road, St. John's Wood, N.W.—Gynæc. Surg. Also Radiologist.
Hospital for Epilepsy and Paralysis, Maida Vale, W.—Hon. Asst. S.
Hospital for Sick Children, Great Ormond-street, W.C.—Part-time Jun. Cas. O. At rate of £150.
Hull Royal Infirmary, Sutton Branch.—H.P. At rate of £160.
Hull Royal Infirmary.—2nd H.S., 3rd H.S. And H.S. to Ophth., &c. Depts. Each at rate of £150. Also Cas. H.S. At rate of £130.
Indian Medical Service.—Commissions.
Inverness, Royal Northern Infirmary.—H.P. At rate of £100.
Leamington Spa, Warneford General Hospital.—Res. H.P. and H.S. Each £165.
Leeds City Sanatorium, Killingbeck.—Med. Supt. £850.
Leicester Royal Infirmary.—Hon. Physician. Hon. Asst. Physician. Also Res. H.P. At rate of £125.
Liverpool Royal Infirmary.—Hon. Surgeon to Lock Dept.
Liverpool Sanatorium, Delamere Forest, Frodsham.—Asst. Med. Supt. £250.
Manchester Royal Infirmary.—Asst. Surg. Officer to Gynæcological Dept. £35.
Manchester Royal Infirmary, Central Branch, Roby-street.—H.S. £100.
Margaret-street Hospital for Consumption, 26, Margaret-street, W.—Hon. Asst. Physician.
National Hospital, Queen-square.—Hon. Surg. Asst. Also Hon. Asst. Surg.
Nottingham General Hospital.—H.S. At rate of £150.
Poplar Hospital for Accidents, East India Dock-road, E.—Sen. Res. O., &c. £200 plus £75.
Preston, Sharoe Green Hospital, Fulwood.—Jun. Res. M.O. At rate of £104.
Prince of Wales's General Hospital, N.—Asst. Pathologist. £200.
Rochester, St. Bartholomew's Hospital.—H.P. At rate of £175.
St. Mark's Hospital for Cancer, Fistula, and other Diseases of the Rectum, City-road, E.C.—H.S. At rate of £75.
St. Mary's Hospital, W.—2nd Asst. Pathologist. £250.
Salford Royal Hospital.—Cas. H.S. At rate of £125.
Sheffield, Jessop Hospital for Women.—Three Asst. H.S.'s. Each at rate of £100.
Sheffield Royal Infirmary.—H.P., H.S., Asst. Aural and Ophth. H.S. Also Asst. Cas. O. All at rate of £80.
Sheffield, Winter Street Hospital.—Asst. Tuber. O. £350.
*Southampton, Royal South Hants and Southampton Hospital.**—Sen. H.S. £225. Also H.P., and Two Asst. H.S.'s. Each at rate of £180.
Southgate Urban District Council.—M.O.H., &c. £800.
Swansea County Borough.—Asst. M.O. £600.
Swansea General and Eye Hospital.—H.P. £150.
Swansea Hospital.—Sen. Res. O. £300.
Walsall General Hospital.—H.S. At rate of £150.
Warwick, King Edward VII. Memorial Sanatorium, Hertford Hill.—Sen. Asst. M.O. £275.
Weston-super-Mare General Hospital.—Res. H.S. At rate of £150.
Wrexham and East Denbighshire War Memorial Hospital.—Two Res. H.S.'s. Each at rate of £150.

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Cranbrook (Kent).

* The salary for the post of House Physician to the Royal South Hants and Southampton Hospital, which is £180 per annum, was given in error in our advertisement columns last week as £120. The correct salary was, however, noted in this column.

NOTES, COMMENTS, AND ABSTRACTS

THE FUTURE OF THE MEDICAL CURRICULUM.*

BY LINDSEY W. BATTEN, M.B. CAMB., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE EAST LONDON HOSPITAL, SHADWELL.

WHAT, precisely, is intended to be the end-product of the medical curriculum?

There are two possible answers. It may purpose to train men for the practice of medicine, its end-product being men and women ready to practise. Or it may profess no more than to teach the principles of our art, to teach medicine and surgery in the abstract as provinces of knowledge; so that if some young practitioner, finding deficiencies in his armament, rounded on the curriculum, like Omar's pots on the Potter, and endeavoured to call that august being to account, the Curriculum might reply: "I never promised to make a practitioner of you, you have learned the science and theory of medicine, apprentice yourself to a practitioner of experience and he will teach you the art." If this position is in fact tenable, much of what I have to say falls to the ground; but in these days of a training period six years long or more, and of a curriculum which includes, besides other practical clinical work, the giving of anæsthetics and the actual conduct of labour, it cannot, I think, be seriously contended that the purpose of our education is other than to prepare us for practice.

I think too—though this is perhaps debatable—that the ordinary standard product of the works must be intended to be general and not special practitioners. Later on, no doubt, modifications may be made in the body and fittings even to the extent of removing it from the chassis and substituting a brand new body of some highly specialised kind. It is right, too, that the workshops should be able on occasion to build what the jargon of the day would call "super-models" for international contests. But to drop the metaphor, no one will seriously contend that it is the chief or the most important business of medical schools to turn out specialists and eminent consultants; their chief business is to turn out good doctors. If this argument is sound we may reasonably and pertinently ask how far the training we received has, in fact, fitted us for practice. Did we enter practice so well equipped that only those things which it belongs to experience to teach were lacking? Did we find that our equipment, though good in patches, was inexplicably incomplete in some respects and in others complicated and cumbersome, including a six-inch howitzer in place of a rifle and a mechanical concrete mixer instead of a spade? Or have we had so much to learn and to unlearn that we would like to grasp this sorry scheme of things entire, to shatter it to bits, and then remould it nearer to our heart's desire?

Few of us, I imagine, would run to this last extreme. If we believe ourselves competent we must in fairness give credit both to our teachers and our teaching. There are no "self-taught" in our profession, and each of us, I suppose, daily recalls with gratitude some at least of those who laboured to instruct him and would gladly remember more of what they taught.

Furthermore it was all extremely enjoyable. I suppose it is common for young men to enter any skilled trade or profession more because the learning of it looks attractive and holds a promise of initiation into mysteries than because he clearly sees himself earning his living in its practice. Ask any elementary schoolboy what he would like to be and, if he answers at all, he will invariably reply "an electrical engineer." He means that he would like to be a powerful magician. The same ambition, coupled very often with a laudable desire to follow in father's footsteps, urges, lures, or gently wafts the erstwhile schoolboy on to the road that leads to medical practice. He enters on his studies with zest and enjoys them. Whether he ever looks further ahead than the date of the next examination may be doubted, and it must be confessed, I think, that he is very seldom invited to do so. I cannot help thinking that, at least in the last two or three years of the course, he might, with advantage, be urged to take a longer view. Be that as it may, there is no doubt that for the present he enjoys being a medical student and uncritically accepts the curriculum as he finds it.

The Student's Progress.

Elementary chemistry and physics are not very exciting, but can be learnt after a fashion with no great effort and still more easily forgotten.

The course in biology, on the other hand, stimulates thought and imagination, and one would like to know what master hand devised it. However much its details may be forgotten it leaves in the mind an enduring sense of the unity of Nature, of the reality of evolution and of man's kinship with other living things. Somewhere between the dog-fish and the rabbit the young man feels that now indeed he is initiated into the mysteries and is an entered apprentice to medicine.

Anatomy attracts the mind as a difficult but still possible memorising feat, presenting also opportunities for craftsmanship to the dexterous; but even its surgical applications are hardly for a moment considered, its medical applications never; nor, in my experience, is it ever suggested to the anatomy student that an occasional visit to the post-mortem room would help to correct and vivify the desiccated and somewhat distorted simulacrum of the human body presented to him in the dissecting room, and would help to preserve his sense of proportion, at a time when it needs all the help it can get.

Physiology, like biology, is, or should be, an inspiring subject. Here is a living science, moving, advancing with strides. The frontiers of knowledge with explorers at work on them are reached in a day's journey from the base; it becomes apparent that research—at least for one with inexhaustible patience and an assured private income—must be an enthralling occupation, and to play at being a physiologist while time serves is pleasant enough. How ingenious are the theories of colour-vision! With what cunning have the experimenters endeavoured to solve the riddle of the renal tubules! How intricate is the minute anatomy of the central nervous system, and what an intellectual feat to visualise it and commit it to memory (though it seems odd that this province of anatomy should be called physiology)! Clearly we shall be very clever doctors when we know all this, cleverer much than the generation who preceded us, whom we begin now to suspect of being seriously handicapped by their ignorance of the latest laboratory work on the rabbit and the dog. True, most of what we learn applies immediately to the smaller quadrupeds, and we hear little, or at any rate much less, about the workings of intact human beings, but perhaps they are only large-scale guinea-pigs, or perhaps we shall come to that; anyway there is quite enough to learn as it is, what with thrombin and thrombokinase, creatine and creatinine, bilirubin and urobilin, tyramine and tryptophane, the visual purple, and the deep connexions of the red nucleus.

Filled to the brim or over, stuffed (I am impelled to say) with facts anatomical and physiological, the young man enters the surgery and the wards. Very

* Based on an address from the chair at a meeting of the Hampstead Division of the British Medical Association on Oct. 9th.

refreshing and stimulating it is to stitch up cut heads without inquiring what makes the blood to clot, very inspiring to find oneself actually in some degree responsible for the treatment of real flesh-and-blood patients. It is a glorious moment, but shadows of the prison house begin to close. Bacteriology, histology, biochemistry, pharmacology, even helminthology rise up like the thorn-trees before the sleeping beauty's prince, until medicine is obscured by its subsidiary sciences and the patient concealed behind the supposed reality of his disease. Apart, too, from the time spent on subsidiary sciences, that spent actually in clinical study is rather curiously apportioned; but of this more hereafter.

Attainments of the Graduate.

Behold at last our young man qualified. He has satisfied the examiners in the preliminary sciences, he has diligently attended the practice of the various departments of a hospital, he has conducted sundry labours, he has satisfied more examiners, and he is, say, six years older than he was when he began his studies. Let us give him one more year to hold a house appointment (for his father's purse is almost empty), and let us then take stock of the situation. How far is he now fitted to become a good general practitioner?

He has made a fairly serious study of two sciences—anatomy and physiology—and has dabbled in at least eight others (it would be easy to increase the number by meticulous subdivision). An almost incredible number of facts more or less related to medicine and surgery have been loaded on to his long-suffering memory and carried by it for a longer or shorter distance. He has known in what form manganese occurs in nature and how sulphuric acid is manufactured; likely enough he has had by heart the atomic weights of the elements. He has known the branches of the internal maxillary artery ("try my superior ink made to prevent blots, &c."), the components of the otic ganglion, and the relation of the structures passing through the sphenoidal fissure ("four fat ladies sitting nipping inferior sherry wine"). He has known the spectrum of methæmoglobin, which organisms liquefy gelatin, and whether *Bacillus paratyphosus* B. forms acid and gas in mannite. He has known the details of Chopart's amputation, and has been able to identify a Murphy's button in the examination in surgical morbid anatomy. He has spent an enormous amount of time getting these and hundreds of other facts by heart against the day when the examiner should cry "stand and deliver." Fortunately, as some may think, he does indeed empty the saddle-bags, which else would be quite intolerably cumbersome and heavy. He turns the stuff out of them as readily as once he lightened himself of the Latin genders and the Greek irregular verbs, and travels on with hardly more of permanent luggage than at the outset of the course. But the time spent in loading up and the labour spent in carrying this unnecessary burden of unsorted facts no one can give him again.

Fortunately he has learnt much beside facts. He has learnt the methods of experimental science, the nature of scientific evidence, and the necessity for controls. He has learnt (we will hope) how transitory are theories, how insecure the foundations of knowledge, how vastly greater the unknown than the known. He has learnt to handle a test-tube, a scalpel and a microscope; he knows something of the complexity of animal structure, the intricacy and mystery of its workings, the ways in which it may be expected to react to stimuli. He has been in fairly close contact with a large number of patients, he has learnt to take a history and to make a physical examination of the more easily accessible regions of the body. He has seen many obscure systemic diseases investigated and diagnosed, and a few common ones; he has attended at a great many abdominal operations, and performed a very few minor regional ones; he has skimmed through certain of the special departments, but has thought them to be, as their name seems to imply, rather the province of specialists. He has perhaps caught a glimpse in passing of the massage department, and has wondered what exercises are performed with the help of that rather exciting-looking gymnastic apparatus; he believes there is something called electrical treatment which you order in cases of paralysis, and he knows there is something called good nursing which is of importance in pneumonia and typhoid.

His year as a house man has probably taught him more, from the practitioner's point of view, than the preceding two years put together; and let us grant at once that if he has time and money enough to be in turn house physician, house surgeon and the house officer of a special department he will be a well-educated doctor; but this can happen only to the few and he is fortunate if he can hold one appointment at his own hospital. Even this is not quite pure gain, for at least in some, and I suspect in many hospitals, there is a tradition that the house man shall regard himself as already a specialist. Is he a house physician? Acute abdominal pain is scarcely his province. A house surgeon? The chest is not his department and he disdains the stethoscope. Is he either of these? The state of the tympanic membrane is hardly a thing you would expect him to investigate. These fictions may even form the basis of a kind of game, a sort of many-cornered tennis in which the patient is the ball. Many of us must have played it, in the days of youth, many of us must have heard from patients that it is still in vogue; but it is a bad game, for apart from the tribulations of the unfortunate ball, it is very bad for the players, whether they play in after years an all-round or a special game, and it is not too easy to get rid of the narrowly specialised outlook which is apt to be formed at this time.

At long last the young man bids a final farewell to examiners, teachers, medical school, and resident quarters, and enters on the independent practice of his profession.

The Limits of the Normal.

There are, of course, many varieties of medical practice and their requirements differ. I will try to confine myself to criticisms which are at least widely applicable, though they may apply rather more to general than to specialised kinds of practice. The notorious complaints that the student is not well trained in practical midwifery and knows little of what is called infant welfare need not be pressed home in detail, for they are but part of a much wider accusation which may be made. The young practitioner, if he is at all self-critical and observant, will find, and will keep on finding, that he knows lamentably little of normal men, women, and children and their bodily functions, and this in spite of the years he has spent in studying anatomy and physiology, intended presumably to teach him this very thing. This truth I began to perceive within a few months of qualifying, when I noticed (as did others) that a large number of army recruits had pulse-rates much in excess of what I had been taught was "normal" but suffered no inconvenience from their tachycardia; and it was last rubbed into me a month ago when I learnt from a patient, with a chart to back the statement, that the body temperature in women rises half a degree or more above normal in the week preceding menstruation. (This, she told me, is common knowledge in sanatoriums.) In the intervening years my conception of the limits of the normal has been constantly widening and my respect for the power and influence of personal hygiene constantly increasing.

The trouble is that the anatomy we learn is a cadaverous anatomy and the physiology a laboratory physiology, but little of it strictly human and none of it clinical. The student goes not only into the wards but into practice quite unfamiliar with the clinical aspect of normal human beings. He does not know how they grow up or how they grow old, on what diets they can live and thrive, what are their

requirements in the way of sleep, exercise, and clothing, and what effects on their bodily functions may be produced by different mental and physical environments, occupations, and habits. This is partly because experimental clinical physiology is as yet in its infancy and much of what might be discovered is still unknown, but it is partly because what knowledge there is is not collected and taught. If he has at all considered anatomical and physiological types, it is only in terms of that precocious and airy science called endocrinology; it has never been hinted to him that he will have, as a matter of daily practice, to try to separate what is inherited and constitutional in a given clinical picture from what has been acquired. It may be said this is an obscure and difficult subject, but so are biochemistry, bacteriology, and the aforesaid endocrinology, to all of which he is invited to apply his poor wits.

All of us must have seen many times cases in which some anatomical peculiarity, some postural fault, or some disorder of function due to a lack of harmony in or around the patient has been diagnosed as an organic disease to the detriment of the patient and the discredit of the profession, and I cannot help thinking this will continue until a course in clinical physiology is introduced into the curriculum in which the student will see and examine as many different kinds of normal human being as can be collected for demonstration.

The Mind and its Disorders.

Closely related to this is the neglect of psychology. There are a few signs that this is beginning to be rectified, but I think it would be hard to deny that the present tendency of medical education is to send the young doctor into practice a more or less conscious materialist.

Almost the only teaching the young man receives about the mind concerns its extreme and gross disorders. So much is this so that the word "mental" has in common speech become almost inverted in its meaning, and when a nurse announces to us with bated breath that "she really thinks the patient is slightly mental," we understand her to mean not that he has glimmerings of reason or that his mind is having a slight influence on the course of the illness, but that he has lost his reason. Further, it is only with the utmost caution that we can speak to a patient about his mind (calling it by its name) unless we want him to think we suspect him of insanity. This, I believe, is because for some time past it has been vaguely but generally understood that medicine was not on speaking terms with the mind—cut it dead when they met and had been heard to say that it did not exist. This trouble must go back some way. "Canst thou not minister to a mind diseased?" asks the distracted Macbeth of his wife's medical attendant, obviously expecting the answer *no*. Sure enough he gets it. "Therein," says the doctor, rather shocked at being asked, "the patient must minister to himself." "Throw physic to the dogs," says Macbeth, "I'll none of it." A very intelligent sentiment, for a physic which cries off as soon as mind is mentioned is worth but little to the human patient, though it may be useful enough to the canine.

As a philosophic theory we may, if we like, argue, or even believe, that mind is not, that thought is only the tune our brains play when stimuli strike their keys and that its quality is determined by the ductless glands. But whatever its ultimate value—and I think it much too facile and shallow-seeming to be true—such a theory is in practice a bruised reed on which if a man lean it will go into his hand and pierce it. The word *mens* was not invented for nothing, and there is no fact which more obstinately confronts us in practice than the fact that our patients have minds, that with their minds we have to deal, and that we overlook or disregard them at our peril and theirs. Many come to us frankly because they are anxious or afraid; another large group complain to us of symptoms demonstrably due to anxiety, unhappiness, or social maladjustment; the ailments of others, trivial in themselves, acquire a large importance from the charge of fear which they carry; and of the rest, perhaps a minority, who have frank organic disease, it may be said that the course of their malady will always be influenced and sometimes determined by their mental attitude to it. Only when a patient is deeply anæsthetised may we for a moment forget his mind, perhaps not even then.

This plucking from the memory of rooted sorrows, disdained by Lady Macbeth's physician, is a task we are asked to attempt far more often than to pluck a malignant growth from the rectum or even a sebaceous cyst from the scalp. It is not an easy task, but it can be attempted and with much better hope of success if we have learnt something of the natural history and behaviour of rooted sorrows and what means are available for their evulsion. The doctor of Dunsinane lost his distinguished patient a few days later, her husband remarking, again rather shrewdly, "she should have died hereafter."

It is quite true that the subject is not an easy one to teach and that the wards of a hospital are not the best place to teach it in; but it is a subject which lends itself better than most to the method of teaching by lecture, and the medical casualty department of every hospital teems with examples of the common neuroses some of which the student might, with great advantage, be set to diagnose. Even if he got no further than to demonstrate to his own satisfaction that some kind of anxiety or fear was the cause of the symptoms he would have learnt much, and from time to time a specific cause for the trouble might be discovered even in the out-patient department and perhaps be dealt with or removed. At present I think it must be admitted that the much-abused word "functional" is suffered to pose as a diagnosis, and, what is worse, to carry with it the implication that none but palliative or placative treatment is indicated. The time, I hope, will come when the word "functional" will no longer be employed as a polite synonym for "psychogenic," and when it will be recognised that though organic changes in the tissues must often be irremediable a disorder of function should be rectifiable.

Function and Structure of the Curriculum.

One more defect in the curriculum must, I think, have come home to many of us. The student who is preparing himself for general practice may not unreasonably suppose that it is in the so-called general wards and in the departments devoted to undifferentiated medicine and surgery that he will find the kind of case he will most commonly meet in practice, and that the special departments are chiefly of interest to those who propose to specialise. The curriculum and the examinations both tacitly support this view. When he comes to practise he finds that whereas general systemic diseases and abdominal catastrophes are uncommon, diseases and disorders of the ear, nose, throat, skin, eye, and limbs, to say nothing of diseases of children and disorders of women, occur every day. Could we have our time again I fancy many of us would allot it very differently.

But it is easy to multiply criticisms. Is it possible to sketch out a revised curriculum? Could the practitioner conspire with Fate or with the Conjoint Board or any other of the gods who control our educational destinies, how would he set about the remoulding? This depends, of course, on what view he takes of his own functions.

"There are men," said R. L. Stevenson, "and classes of men that stand above the common herd: the soldier, the sailor, and the shepherd not unfrequently; the artist rarely; rarelier still, the clergyman; the physician almost as a rule. He is the flower (such as it is) of our civilisation; and when that stage of man is done with, and only remembered to be marvelled at in history, he will be thought to have shared as little as any in the defects of the period, and most notably exhibited the virtues of the race. Generosity he has, such as is possible to those who practise an art, never to those who drive a trade; discretion, tested by a hundred secrets; tact, tried in a thousand embarrassments; and what are

more important, Heraclean cheerfulness and courage. So it is that he brings air and cheer into the sick-room, and often enough, though not so often as he wishes, brings healing."

It seems that the Emperor Napoleon had, as personal physician, one Corvisart, for whom he had a high regard. "Medicine," says Corvisart, "is not the art of curing diseases; it is the art of treating them, with the hope of curing them, and of soothing and satisfying sick people." "The doctor," he says again, "ought to be on his guard against the itch to explain everything. He ought to know that Nature, hidden in most of her works, is especially so in diseases." Both these writers emphasise the fact that medicine is an art; Stevenson contrasting it with a trade, Corvisart with an exact science. Corvisart's reflections are the more apposite to my present purpose, but Stevenson's high praise is worth noting, if only because it shows for what we are most valued by some at least of our patients. We should be surprised to find such things said about us in these days of scientific medicine. The point I wish to make is that medical practice, whatever may be said of medicine, is an art, an art and a craft, not a science; and though many may run to and fro and knowledge be increased, an art it will and must remain. We are of value to our patients most for what we are (and were no curriculum can help us), next for what we can do, somewhat less for what we know, and least for what we can, or think we can, explain. Research, as has been lately pointed out, whether in the laboratory or at the bedside, is only to a limited degree compatible with any kind of practice. Either of them is able to absorb the time and energies of any ordinary man, the aims and methods of the two, and the intellectual qualities and mental outlook they require are diverse and often conflicting.

New facts and new remedies will continue to be discovered in the laboratories and new theories formed there; they will be handed out to the practitioner who will receive them, let us hope gratefully enough but with a certain scepticism, doubting," like Corvisart, "the value of a drug (or other remedy) to which many virtues are attributed, especially if these virtues are of an opposite character"; will weigh them in the scales of reason and experience, try out those which have the air of truth, dispense that which proves good and reject that which proves worthless. The last word as to worth and truth will generally lie with him. The day is not distant when the wise patient will apply direct to the scientist for diagnosis or treatment.

What Should be Taught.

The curriculum of my hopes, the good practitioner's curriculum, will lay more stress on experience and less on learning; it will impute far more value than at present to technique and skill of hand; it will be far more discriminating in its choice of facts to be learnt, and will be chary of teaching any theories at all.

The young man in this golden age to be will attend few lectures, for they will be strictly confined to matter not to be found in books; he will learn an anatomy imbued with a sense of proportion, paying regard to what is clinically important and what is not; an anatomy, too, constantly mindful of the relation of structure to function. It will be made quite clear that certain anatomical facts which experience has shown to have little or no clinical value are not to be memorised and will not be asked in examinations, though the list of these facts will be long. Thereby the justly famous mnemonics will perish from the earth, but we cannot have everything. Lest this lead to slovenliness stress will be laid on good and careful dissection and far more marks will be given for the practical than for the written examination. Radiographic anatomy will be studied at the same time as anatomy "in the round"; the student will learn the anatomy of fractures and dislocations while he is dissecting the limbs and will visit the post-mortem room while he is exploring the thorax, abdomen, and brain.

The judicious pruning of physiology will be a more difficult matter but here, too, it should prove possible to eliminate the memorising of many unimportant facts, and of names, bygone experiments, and exploded theories, and to make room for that course in clinical physiology of which I have spoken. The tiny seed of this course is to be found already in the curriculum where the student of physiology is required to learn the use of the ophthalmoscope, the perimeter, and the sphygmomanometer, but the seed is an unconscionable time in germinating. When it does at last put forth its leaves and fruit he will learn to make a complete clinical examination of healthy subjects and to record the results, employing not only the ophthalmoscope but all such "scopes" as may be reasonably employed in health as well as his unaided senses. The work done will resemble in part the work of child welfare centres, in part the examination of candidates for life insurance or recruits for the Air Force, and it will be combined with research into the limits of the normal. This course should serve to bridge effectively the gap, at present so awkward to negotiate, between the class-room and the wards. There will be no shock in the change, no temptation to forget what has been learnt, little to learn in the examination of sick patients, and much less danger of mistaking the unusual for the pathological.

In his clinical years our student will spend more time with patients, less time in the museum, the library, and the laboratories, and very little time in the operating theatre. He will be taught that while he cannot be expected to know all about his patient's disease he must know all about his patient. At every stage of his career he will be prohibited from specialising; in vain will he disclaim all knowledge of heart or lung in a surgical, of ears and nose in a medical, ward; he may not know what is wrong with them but he must examine them and report what he sees and hears. The special departments will be commended very strongly to his notice. He will attend a fracture clinic and work in it with his own hands; he will learn to pass the Eustachian catheter, to perform a myringotomy and to wash out an antrum; he will learn to put a limb in plaster and something of orthopœdic shoemaking, and will himself practise remedial exercises; he will apply a starch poultice to an impetiginous head and Unna's paste to varicose ulcers; he will perfect himself in the art of bimanual palpation of the uterus; he will write a diet sheet for a child with rickets and another for one who has bilious attacks; he will be attached as clerk to the casualty physician and write his prescriptions for him in full; he will inject varicose veins and piles and give transfusions of blood.

All these accomplishments and many others like them could be taught at least as easily and as safely as the giving of anæsthetics or the conduct of labour. All are of more value in practice than much of the book-learning which now so largely supplants them; is not even the meanest of them of more use, as between doctor aud patient, than any knowledge of the properties of suspensoid and emulsoid colloids which the student is likely to acquire or to retain? All are at least embarrassing and at most impossible to acquire in the world outside, yet I think it must be agreed that the student who has learnt these things in hospital has had rare good fortune.

At his final examination our student will not be dumbfounded if he is asked to describe the common types of dyspepsia, their ætiology and treatment; a question on tonsillitis, on influenza, or acute otitis media in a child will not surprise him, nor will he think it unfair to meet as a "short case" a patient suffering from sciatica whose dental radiograms he will be expected to demand and whose antra he will be wise to trans-illuminate.

In a still more golden age the student will be marked like a schoolboy on his term's work and examinations will become relatively unimportant; their written parts, I think, will largely disappear, and the practical and viva voce examinations will be

planned to test thoroughness in examination, clinical experience, and acumen, manual dexterity and perhaps even skill in handling garrulous, reticent, or otherwise difficult patients. But without any such revolutionary change I suggest that a student taught and trained in the way I have tried to outline would be likely to prove, in plain English, a better doctor than one trained in the present régime. He would be less tempted to cry out in every crisis for help from a laboratory test, from a complicated diagnostic machine, or from a specialist; he would be better able to stand up as a man should against that brown and sticky torrent of false science which pours unceasing through our letter-boxes; less burdened with the findings and the theories of the sciences he would have at heart more of the spirit of a scientist; best of all, he would be of far more value to his patients in their troubles and would rise both in their esteem and in his own.

WHITAKER 1931.

THE 63rd annual volume of the Almanack first issued by Joseph Whitaker, F.S.A., in 1868, contains the astronomical and cosmic data with which the year-book was started, the value of which the average reader may be apt to overlook, for grafted on to it is a vast amount of information respecting the government, finances, population, commerce, and general statistics of the various nations of the world. We have taken this description from the familiar title page with the zodiacal signs and seasons, as it cannot be bettered. The editor-in-chief of the Almanack tells us he has used many suggestions made by correspondents and expresses gratitude for favours to come (perhaps he would insert our present address correctly); but it would require a very bright boy or girl to find an omission in the 1931 Whitaker, although it would do him (or her) good to try, and incidentally he (or she) might get mentioned in 1931, for was it not Miss Venetia Burney, aged 11, who proposed for the newly discovered planet the name Pluto, which has been accepted by the trustees of the Lowell Observatory. No one would go to the Almanack for medical information, but there is a useful classified summary of metropolitan hospitals (pp. 400–406), and in the advertisement columns there are many entries under hospitals and institutions, to which the proprietors have added the kind note "The hospitals and institutions given in this section deserve the heartiest and most generous support it is possible to give." The Almanack is published in two editions, one bound in red and green cloth, containing 960 pages, at 6s., the other bound in orange paper cover, at 3s., which omits information about colonial and foreign countries as well as the annual summaries which form so interesting a feature of the larger work.

NEW PREPARATIONS.

QUINISAN (Messrs. Howards and Sons, Ltd., Ilford) is a new quinine salt—the bi-salicylosalicylate—which is identical with the U.S.A. quinisal. It is a definite combination of quinine and salicylic acid forming a crystalline powder which is insoluble in water, but which separates into its constituents in the stomach and intestines. The firm has received considerable medical evidence that the preparation has been valuable in the treatment of catarrhs, influenzal or otherwise, and early tonsillitis.

(1) NORMACOL, (2) RAMINAL (Messrs. H. R. Napp, Ltd., 3 and 4, Clement's-inn, Kingsway, London). (1) This preparation is an intestinal evacuant of vegetable composition, and mild in action. The manufacturers adduce, as a test of its bulk-forming and emollient character, the fact that one teaspoonful of granules will absorb five ounces of water in about four hours, with the result that a gelatinous mass is yielded. The sample received by us does not claim to be a novelty, but the manufacturers point out that considerable improvement has been effected in its flavour, and this is a distinct point to its advantage. The dose, as given on the supply tins, is from one to two teaspoonfuls for the adult and half that quantity for the child, but the wise instruction is included that, while the quantity may be increased if required, the dosage should be regulated by the doctor.

(2) Raminal will be sent free of charge to medical practitioners who may desire to make a trial of it. It is a blend of theobromine calcium salicylate with chlorophyll and phosphate of iron, and its components indicate the particular action it may be expected to have in anæmia and hypertonic conditions. It is supplied, to the medical profession only, in boxes of 50 tablets.

THE PRINCIPLES OF DIET.

A NEW and revised edition of Lindsay and Mottram's "Manual of Modern Cookery" (London: University of London Press. 1930. Pp. 316. 4s. 6d.) contains an introduction to the principles of diet which should enable anyone who uses the manual to do so intelligently. Left to himself, it is stated, the average person of means takes a diet which, as regards its chemical composition and energy value, is constant throughout temperate regions; nevertheless, although instinct may be a wise guide, grave dietetic faults are often committed by the sanest of people. The commonest example of this is seen in the results of upsetting the balance between fats and carbohydrates. If we take too much fat or too little carbohydrate our health is promptly upset; malaise, nausea, and actual sickness may result; or we suffer from trouble which may be vaguely diagnosed as biliousness or sick-headache. Intelligent users of this manual will not err thus. There are, it is added, more than hints of a necessary balance between protein and vitamin B, between protein and calcium, and between cereal foods and vitamin D. The question arises, is this recognised by those who prepare our meals? and the remainder of the chapter is an answer to this inquiry. The chapter on the principles of cookery is of equal value, and each of the remaining 250 pages of the book contains three to six clear concise descriptions how to prepare almost any kind of food. A table of contents at the beginning makes reference singularly easy.

Births, Marriages, and Deaths

BIRTHS.

ANDERTON.—On Dec. 9th, at Moresby House, Hindley, Lancs., the wife of Dr. Reginald Anderton, of a daughter.

DOUTHWAITE.—On Dec. 10th, at Harley-street, W., the wife of Dr. A. H. Douthwaite, of a daughter (stillborn).

HOUGHTON.—On Dec. 10th, the wife of L. Wynn Houghton, F.R.C.S., Elvyne, Berkhamsted, of a son.

SALISBURY.—On Dec. 7th, at Woodlands, Billing-road, Northampton, the wife of Walter Salisbury, M.D., M.S., F.R.C.S., of a daughter.

MARRIAGES.

MAYBURY—LYALL.—On Dec. 11th, at St. Giles's Cathedral, Edinburgh, Bernard Constable Maybury, F.R.C.S., to Isobel Wilson, elder daughter of Mr. and Mrs. George Lyall of Torbruad, Turriff, Aberdeenshire.

DEATHS.

DESPARD.—On Dec. 8th, at Yarmouth, Isle of Wight, Rosina Clara Despard, M.D.

FAIRBANK.—On Dec. 9th, at George-street, Hanover-square, W., John Fairbank, M.R.C.S., aged 85.

GARDINER.—On Dec. 9th, at Dunmow, Joseph Napier Gardiner, M.D., F.R.C.S., L.R.C.P., aged 59.

MACK.—On Dec. 11th, at Windmill-avenue, Ewell, Surrey, Hans Hamilton Mack, B.A., L.R.C.P., of Sydney, N.S.W., aged 69 years.

NIALL.—On Dec. 12th at "Kinkora," New-road, Chatham, William George Niall, M.D., M.Ch.R.U.I., aged 68 years.

PINTO-LEITE.—On Dec. 12th, at Fellows-road, N.W., Dr. Hubert Pinto-Leite, aged 51.

STIDSTON.—On 15th inst., Charles Algernon Stidston, D.S.O., M.D., beloved husband of Olive Stidston, of 14, Waterloo road, Wolverhampton, aged 49.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

GIFT OF A HOSPITAL.—An anonymous donor has offered to defray the cost of a new hospital at Driffield, East Yorkshire. The site was given and a tender of £800 has been accepted.

ADDRESSES AND ORIGINAL ARTICLES

THE CONCEPTION OF "NERVOUS DISORDER."*

BY MILLAIS CULPIN, M.D. LOND., F.R.C.S. ENG.,
LECTURER IN PSYCHONEUROSES, LONDON HOSPITAL MEDICAL COLLEGE, AND IN MEDICO-INDUSTRIAL PSYCHOLOGY, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

THE differences of attitude within the ranks of those dealing with medical psychology are small in comparison with the differences between their general outlook and the outlook of those of our profession who do not deal with that subject. Most of us regard that difference of outlook as marking the clash of new ideas and old prejudices, and anyone familiar with the resistance that met the pioneers of psycho-analysis must agree that prejudices of a special quality were aroused by the nature of their discoveries.

Freud disturbed the peace of the world, but, having admitted that, I propose to show that the clash did not begin in 1895. The paper of my colleague Miss May Smith (on the Nervous Temperament) [1] led me to see how the pendulum has swung between the two schools represented at one time by vitalists and mechanists, at another by animists and iatro-physicists, nominalists and realists, and now by psychologists and neurologists, for, despite efforts at reconciliation, we must own that the outlooks of the last-named pair upon a case of hysteria are fundamentally different. Freud, who was primarily a neurologist, has admitted that his neurological knowledge was useless in his work upon those clinical problems that he has done so much to solve. What is the history of these attitudes and how have these problems come to be expressed in neurological or pseudoneurological language?

Such language cannot be avoided, and I find myself speaking of "nervous" patients, whilst agreeing with Dr. Johnson, who, in 1783, wrote of "a tender, irritable, and, as it is not very properly called, a nervous constitution." The language, too, possesses infinite possibilities. In an official report in 1911 on Telegraphists' Cramp, there occur "nervous instability," "neurasthenic temperament," "nervous disposition," "permanent nervous weakness," "nervousness of temperament," and "nervous type." Other variants are neuropath, psychoneurosis, and neuropsychosis, neurosis and neurotic, nervous debility, nervous exhaustion, nervous breakdown, and less well-known gems such as neuro-mimesis and cerebro-cardiac neuropathy. The growing popularity of neuritis—a comparatively rare disease in hospital out-patient practice—makes me fear that, like a good apple among rotten ones, "neuritis" will find itself among the throw-outs.

Here, then, is a terminology of inexactitudes that calls for inquiry as to its origin, and since it must express some general conception the history of the terminology and of the conception may be taken together. Here I shall make use of material from Miss Smith's paper.

Early Conceptions of Disease.

Starting with Hippocrates, we find the conception of the "physis," a term difficult to translate but appearing to mean the organism as a whole or perhaps something behind the organism, from which the word "physiologist" is derived. To quote from Brock:

> "The Greek masters of medicine observed, as do our experienced clinicians and practitioners still, and as our laboratory specialists increasingly fail to do, that the living organism under natural conditions acts primarily as a whole, and that the actions of its parts are naturally subordinated to this supreme function."

And again:

> "The physis is not secondary to the corpuscles, but a long way prior to and older than they . . . it is the physis which puts together the bodies of plants and animals by virtue of the faculties which it possesses . . . . And when they are born it provides for them by the use of, again, other faculties—one of affection and provision for offspring, one of companionship and friendship for kin."[2]

The physis and the Groddeckian "Es" are not far different, and the paradox emerges that few physiologists would grant the existence of that physis of which they are nominally the exponents.

Galen, who belonged to no school but leaned towards vitalism, gave currency to the humoral pathology of temperaments now enshrined in the words sanguine, choleric, phlegmatic, and melancholic, with the warning that "there is the creative power of nature that shapes parts according to the disposition of the mind."

Behind the humours were forces or influences, the elements as known to the ancients—earth, air, fire, and water. Here is an attempt to express disease and character traits in terms of known forces; we might smile at its simplicity, but there is a craving in us to continue this attempt, a craving that almost demands a physis of its own and so urgent that we again and again invent hypotheses whose only use is to satisfy it. Here is no question of pragmatic value; the function of the hypotheses is not to guide, or to subsume knowledge under a formula, but to satisfy the craving for an answer to the question "What makes the wheels go round?"

Against Hippocrates and the physis may be set up Asclepiades and the atoms. He was described by Brock as a man of vigorous intellect and will, who made up his mind what he wanted, and proceeded to get it, and such a man could have no use for the physis. He took Rome by storm with the theory that all vital functions resulted from the movement of atoms—the latest theory, just introduced to Rome by Lucretius. Brock compares him with one Abrams, of San Francisco, who utilised in a similar way the theory of electrons.

In Hippocrates and Asclepiades are exemplified two opposing attitudes that continue to this day. The medical psychologist, whose training has included a certain minimum of physiology and pathology, is content to stop short at a point where he believes these disciplines can carry him no further, and then attempts to understand his problems by a study of the organism as a whole. What has decided each of us in that attitude would be a delightful subject for investigation. May I recount the discovery of my own attitude? As a surgeon during the war, I was often invited to operate on a patient—with a deformed foot, let us suppose—of whom, after examination according to my training, I would say "No, I won't operate on him; he's doing that himself." It seemed quite simple, and if I had been called an animist my ignorance would have precluded emotional response; if a psychologist—well, we know what the English army did in Flanders. I cannot say why I

* Presidential address to the Medical Section of the British Psychological Society delivered on Dec. 17th, 1930.

did not think out what nerve centres were concerned in the mechanical production of the deformity; I did not trouble then and I do not trouble now. Yet we know that many of our colleagues would study such a case not as a reaction of the man as a whole, but as a "functional nervous disorder," and seek to understand it as a derangement of physiological mechanisms. The difference is fundamental and not to be smoothed away by hopes that some day we shall be able to explain one world in terms of another, to account for hysterical behaviour, disordered hopes and fears, political opinions and gastronomic likes and dislikes, by reference to the central nervous system.

Temperament.

Preserved chiefly by Arabian medicine, Galen's conception of temperaments played a great part at the revival of learning. Each advance in natural science was seized upon as the key to the temperaments and one primum mobile after another served to satisfy the eternal craving. Sometimes the new force was hailed as superseding animism or vitalism, sometimes it was an expression of it; sometimes the neophyte in history is entirely at sea in understanding what the disputants were driving at. Van Helmont (born 1577) made play with the archæus and its relations with fermentation. Sylvius followed with vital spirits that were prepared in the brain by a process of distillation, and used chemistry as the key to all problems. He ascribed most illnesses to acids and his ideas may survive in popular beliefs of to-day. Sprengel, the medical historian, writes: "Thus the most noble of all the arts became the prey of the imagination of the chemists." [3] Miss Smith showed how Stahl, after Harvey's discovery of the circulation of the blood, used the facts to give a mechanistic turn to his animism. "The mind adopts and maintains as its fundamental disposition that particular disposition which the movement of the humours through channels of a definite type has given to the pulse or circulation." The sanguine temperament was due to fluid blood flowing easily through channels broad and wide, resulting in harmoniously operating processes throughout the body.

Stahl has satisfied his craving, and lest we may think his modes of thought differ from those of our age we can find a parallel in 1908.

> "We know what a delicate structure the brain is, and if there be an anæmia, or a flushing (such as we can very often see for ourselves in the vessels of the skin) of the whole or part of the brain—for instance, one hemisphere or one or other of the ideomotor areas—what is more likely than that paresis of the corresponding limbs should result . . . This, in brief, is my view of the pathology of many hysterical disorders." [4]

Stahl was a shrewd observer, and so was this writer; each used for the same end the physiological knowledge of his day, and two centuries have made no difference in their modes of thought, nor in the results of their thinking.

Conveyance of Irritability by Nerves.

In opposition to Stahl's theories came the mechano-dynamic views of Hoffman, who translated the anima into an ethereal fluid, secreted principally by the brain, which draws it from the blood and distributes it by means of the nerves. This paved the way for the application of the physiology of Haller, who discovered the function of nerve in conveying irritability to muscle. According to Sprengel, the medical historian, he built up in terms of irritability his own theory of temperaments; thus "a feeble irritability, joined to an energetic fibre, constitutes the sanguine temperament." [3] My view is that Haller's theory of temperaments, to which he devoted 26 lines in a total of 566 pages, was a by-product to which he attached little value. He believed in the existence of a nervous fluid, a substance that passed along the actual nerves, and a *nervous theory* now sprang up by which "all the phenomena of life, especially the movements of the solids and the mixture of the humours are the results of the influence of the nervous force . . . all the diseases that appear to have as a cause an alteration of the humours depend upon the affection of the nervous system." [3] The nervous fluid, originally supposed to pass along the tubular nerves, has now become a nervous force difficult to distinguish from the old vital spirits. Schaeffer (1782), says Sprengel, "rendered great services to the nervous theory." "He demonstrated that even in the maladies called local the nervous force exercises a powerful influence; that, for example, cancerous ulcers and chronic cutaneous eruptions depend evidently upon feebleness."

What a development from Haller's discovery that nerve conveys irritability to muscle! Sprengel, writing in 1800, ends his chapter on Haller with more than a note of triumph.

> "The vivid light that the theory of excitation has for more than 20 years thrown upon dogmatic medicine has at last shown that all efforts made before then to explain the nature of organised beings were lacking in unity and went beyond the limits of our understanding. . . . Whilst all useless research upon the nature of the vital force has been avoided, there has been demonstrated in the most satisfying way the difference that exists between chemical or mechanical effects and the organic operations of the body. . . . It was reserved for the period in which we live to put an end to our uncertainties, to refute all the theories of the atomists, and to establish pure dynamics upon foundations for ever unshakable." [3]

He goes on to tilt at the still opposing theory of chemical materialism, and then into a discussion of materialism and the immortality of the soul, in which he quotes Voltaire, David Hume, Kant, and Priestley. Some serious matter beyond my understanding is involved in the advocacy of nervous force versus vital force. I cannot identify the nigger in the woodpile.

Sprengel gives, as part of the development of the theory of irritability, the views of Cullen, an Edinburgh physician who edited the translation of Haller's "First Lines," and he leaves us in no doubt as to the influence of Haller. The late Sir Clifford Allbutt was as emphatic about the neglect of Haller, specifically blaming Cullen and suggesting that all he knew about Haller was at secondhand. This contradiction can be understood. Cullen and his contemporaries used Haller's discovery as van Helmont, Sylvius, Stahl, and Hoffman used the discoveries of their day—to satisfy the eternal craving by yet another hypothesis; to Sprengel this was a magnificent feat, to Allbutt it bore no relation to science. He writes:

> "Into Cullen's other works some of the Hallerian teaching seems to have found its way, perchance by the eclectic Gaubius, but of the method and spirit of the great man we find little" . . . "for the hearer of Cullen's physiological lectures Haller might never have existed" . . . "this hollowness makes the medical writers of the latter half of the last [18th] century and the beginning of this seem farther from us than Galen himself, in whom, as F. J. Payne rightly insisted, the true spirit of experimental science was awake."

Whilst admitting all this is justified, we may differ from Clifford Allbutt and maintain that Haller was not neglected, but shamefully misused.[5]

Sprengelian enthusiasm crops up in a survey of medicine up to date by Seelig in 1925:—

> "These studies substituted for the old Hippocratic principle of the 'pneuma,' for the 'Archæus' of Paracelsus, for the 'vital spirits' of Sylvius, for the 'anima' of Stahl,

for all these vague meaningless things these studies of Haller substituted the simple principle of irritability, a force now recognised and experimentally demonstrable in all living tissue. . . . . We may well picture to ourselves the significance of the enunciation and proof of such a far-reaching fact. How many of us might covet the glory of accomplishing as much as this, even after a long life of labour." [6]

The Weltanschauung of 1800 is remote from us, but 1925 is near enough for us to inspect the wood-pile. Seelig's survey contains no reference to medical psychology—not even a thrust at Freud. The nigger emerges as the belief that nerve irritability made psychology unnecessary.

Now for Haller himself. His account of the physiology of nerve and muscle is as modest as it is logical, and he seems to attach to it no greater importance than to his other work. In the chapter on Conception, we read:—

"Thus much concerning the materials; but we are at a loss concerning the formation. . . . We readily reject such causes as a fortuitous concourse of atoms, the blind attractions between the particles of the nutritious juices, and the strength of ferments, inconscious of the reasons why they operate; the soul is certainly an architect unequal to the task of producing such a beautiful fabric; as for internal models, of which I never could conceive one clear idea in my mind, we shall refer them to those hypotheses which the desire of explaining those things, of which we are unwillingly ignorant, has given rise to." [7]

He recognises the craving and shuns it.

Neuroses.

Let us take up the thread again with Cullen. He ascribed to the brain a motive force upon which the strength of the body depends and from which, by its relation to the density and elasticity of the nervous fluid, results the temperament.[3] About 1780 he introduced a word whose subsequent history needs attention, and wrote: "I propose to comprehend under the title of neuroses all those preternatural affections of sense or motion which are without pyrexia, as a part of the primary disease." [8] Among his neuroses were (I quote from Clifford Allbutt) apoplexy and palsy, syncope, dyspepsia, hypochondriasis, tetanus, epilepsy, chorea, palpitation, dyspnœa, asthma, whooping-cough, pyrosis, colic, cholera, diarrhœa, diabetes, hysteria, hydrophobia. The Oxford English Dictionary gives later uses in the first half of the nineteenth century; lead colic was a neurosis, and (1843) "the diseases of function embrace the neuroses, hæmorrhages and dropsies."

In 1874 Maudsley broke new ground in speaking of "Insanity, epilepsy and some allied neuroses;" he equated *neurosis spasmodica* with the insane temperament, defining it as "a defective or unstable condition of nerve element, which is characterised by the disposition to sudden, singular and impulsive caprices of thought, feeling, and conduct." [9] Is this a physiological observation, has it enough practical utility to give it value, or is it another result of the eternal craving? Let us satisfy our own craving by seeking a reason why Maudsley made this excursion into the jungle of pseudo-neurology.

In the early seventies Huxley and Romanes, in setting the affairs of the world upon a mechanistic basis, seem to have wandered into metaphysics. Here is a brain; here are mental processes; what is the connexion? We are all metaphysicians enough to be compelled to believe that every mental activity is related to a neural activity, and Huxley gave to the former the name of psychosis, to the latter the name of neurosis. I shrink from this subject, for when I read that neurosis in the psychological sense signifies "a change in the nerve-cells of the brain prior to and resulting in psychic activity," [8] the attempt to think what that means makes me know what it is to feel like one of Janet's obsessional ruminators; but the Oxford Dictionary supports this definition with quotations from Huxley.

We must remember that this was a time of conflict, a time when Huxley carried on a public controversy with Gladstone about the authenticity of the story of the Gadarene swine. In such a conflict the ranks must close up, and perhaps the dominance of neurosis over psychosis had a significance now lost to us, for the field of theological controversy has out-of-the-way corners. My remembrance of the echoes of that conflict suggests that to admit the psyche could dominate the neuron might have been feared as tending to a final surrender and the acceptance of the story of the swine. We can only suspect the nigger in the wood-pile.

We may conclude that Maudsley was influenced by the philosophical tendency of the period when he gave us this new use of an old word. But his new use had a short reign. Neurosis now means anything the speaker likes, except insanity. When and how this change took place I do not know, but the processes that were once, as it were, the two sides of a shield are now widely separated in their clinical meanings. A man who is irrationally afraid to walk across a field, and acts accordingly, suffers from a neurosis, as does a man with mucous colitis, or an irritable heart; a man who irrationally believes that people are persecuting him, and acts accordingly, suffers from a psychosis—not a neurosis. It is all so very confusing. Huxley was once an examiner, and whoever is tempted to use the word clinically should imagine himself a candidate asked by that vigorous controversialist "What is a neurosis; how would you diagnose and treat it?"

This episode ends with that final triumph of the nineteenth century, the word "neurotic"—an embodiment of pseudo-physiology, unsound metaphysics, and moral condemnation. It often indicates that, since the patient's symptoms do not accord with our hypotheses, he is not really ill but only thinks he is.

The Nervous Temperament.

A "nervous temperament" needs mention. Galen taught nothing about it, but in 1805 Cabanis remedied the ignorance of two millennia by discovering that there are people with whom the nervous system predominates over the muscular. There must be differences of temperament according to the dominance of one or the other, so he devised a nervous and a muscular. The muscular disappeared, but the nervous is still popular enough to justify a brochure by Dr. Smith and myself in which we describe our efforts to identify it.[10]

It must not be thought that all this was unopposed. Sprengel's contempt for the chemists showed the existence of opposition, and the following from the preface to a book by Robert Whytt illustrates a defensive attitude not unfamiliar:—

"The disorders which are the subject of the following observations, have been treated by authors under the names of flatulent, spasmodic, hypochondriac, or hysteric. Of late, they have also got the name nervous which appellation having been commonly given to many symptoms seemingly different, and very obscure in nature, has often made it to be said that physicians have bestowed the character of nervous on all those disorders whose nature and causes they were ignorant of. [We can almost hear the voice of Dr. Johnson].

"If it should be said that to account for diseases from the sensibility or sympathy of the nerves, while we know not wherein these powers consist, is no better than referring them to a *facultas incognita*, or to the hypothetical motions or counter motions of the animal spirits, I shall only answer

that although we cannot explain why grief or joy should, by means of the nerves, excite a greater motion than usual in the vessels of the lacrymal glands, yet it is leading us to the truth and advancing one step farther in our knowledge, to show that the increased secretion of tears, occasioned by those passions of the mind, proceeds from this cause, and not from any compression of the lacrymal glands or their ducts, by the neighbouring muscles, as has been commonly supposed. And to ascend from small things to great, although Sir Isaac Newton did not pretend to explain the cause of gravity, yet he made no small improvement in physical astronomy when from this principle alone he accounted for the various motions of the planets, and banished the imaginary vortices of Descartes, which had been contrived, but unsuccessfully, to explain the phenomena of the solar system." [11]

Functional Nervous Disorder.

In the early part of the nineteenth century the substitution of nervous force for earlier prime movers was unchallenged. Ideas, however, must have become complicated, for in 1868 Beard's popularisation of neurasthenia was hailed as bringing order out of chaos. Beard's view (I quote from Savill) was that the primary factor is over-civilisation, which disturbs the balance between nerve waste and repair, and results in a weakened and unstable nerve force. This, however, is almost the last appearance of the old favourite, and it gave place to a weakened or exhausted nervous system. This survives alongside the newer conception of "functional nervous disorder," which draws upon our increased knowledge of anatomical detail to make a last defence against anything savouring of the heresy of animism.

Yet a sound physiology has existed side by side with these perseverations, and in 1811 Bell wrote an account of the central nervous system that rested entirely upon observation and rigid deduction, with no reference to nerve force or other speculative salve for our ignorance. He wrote:—

"The operations of the senses in rousing the faculties of the mind, and the exercise of the mind over the moving parts of the body, is through the brain and nerves." [12]

Such is the attitude of modern physiology, which is content to regard mind as a useful abstraction and leave it at that. The old craving is, however, still at work, and in a film shown in this country, and recording the experiments of Pavlov, the last picture gave us the news that "Man's behaviour is but a series of conditioned reflexes." Dr. Smith has drawn attention to the modern Count Fosco who wrote, concerning endocrines:—

"These glandular predominances are determining factors in the personality, creating genius and dullard, weakling and giant, Cavalier and Puritan. All human traits can be analysed in terms of these because they are expressed by them." [13]

I absolve my physiological friends from any share in these attempts to pour the products of a recent harvest into a very ancient bottle.

Minor Psychoses.

The theory of "nervous disorder" is a parasitic growth upon scientific medicine; hopes that it may at some future time find more legitimate connexion are a hindrance when we treat them as present realities and, like Sabinus and his sect, invent improbable explanations of things that do not happen.[14] The theory has become limited to a narrower sphere since the days of Cullen, but within that sphere we still give validity to speculative pathology. The acrimonious controversy in which Herbert Page, a sound animistic surgeon, proved, in opposition to Erichsen, that "railway spine" did not depend upon obscure lesions of the cord but was a reaction of the man as a whole, took place in the 'eighties. When the Great War produced a record crop of minor psychoses, there sprang up the theory of shell-shock, and men with hysterical conditions received wound stripes for physical injury. We read about tiny hæmorrhages into the brain, of synapses separated by the force of high explosives, of the effect of gases upon the blood and the nerves. Our friends the enemy produced the same theories. Then, as Ferenczi wrote, "silence fell upon the mechanistic camp." In order that the war might continue, the phrase shell-shock was prohibited, and theories about it were buried with as little fuss as possible. After the war Herbert Page, then an old man, wrote to me a pathetic letter, in which he said that all the symptoms of shell-shock would be found in his book on "Railway Injuries," but that the lesson he had tried to teach had been forgotten. Railway spine survives as traumatic neurasthenia, and we read medical evidence that nerves are shattered as the result of an accident that produced little or no demonstrable trauma.

Glenard's speculations on enteroptosis as the cause of neurasthenia led to pexies innumerable. At one stage it was laid down that no neurasthenic patient should be told he had a movable kidney; he was supplied instead with X ray films with arrows on them showing where his colon and stomach had slipped to Only recently has it been announced that virginal visceroptosis should not be operated upon. The occupational neuroses—nystagmus, cramps, and such like—are supposed to produce nervous symptoms; which is as if the spots produced the typhoid. It is amusing to read of the epidemic of night-blindness in the Continental armies, to which there are some 40 references in the literature, which had cardiac irritability among its many causes. It is not amusing to find night-blindness competing with cardiac instability as a cause of disablement in miners' nystagmus, which costs us over £650,000 per annum in compensation.

My statistical friends do sums about the incidence of sickness under the Insurance Act. You might not think that has any relation to nerve irritability, but here is the sickness experience of printers: "In long-period illness the diseases grouped under the nervous system are the most consistently important. They produce throughout insured life between 30 and 40 per cent. of all the days of disablement and approximately a quarter of all the claims." Turning to the specification of "Diseases of the Nervous System" we find: thrombosis, embolism, insanity, neurasthenia, hysteria, neuritis, epilepsy, neuralgia, nervous debility, vertigo, myelitis, insomnia, chorea, faints, paralyses, tabes, cerebral hæmorrhage.[15]

Having brought the story up to the present day, I hope I have carried out a part of the task I began with—to trace the history that lies behind some modern differences of attitude. I have, however, omitted half the task as being beyond my powers. Some may regard as entirely new the modern observations and theories upon which we, as medical psychologists, are in general agreement; some may see a continuity of descent through earlier lines of thought, and the continuity of the conflict of attitudes makes me incline to the latter view. But the inquirer will meet at every period an emotional emphasis upon differences of theory, for which the contending parties offer no explanation and that may depend upon the spirit of the period as well as upon the fundamental tendency of mankind to externalise his inner conflicts and difficulties. It is this tendency, you will agree, that makes the public cling so strenuously to the belief in mechanical forces as responsible for psychological troubles.

TREATMENT OF LOBAR PNEUMONIA BY FELTON'S SERUM.

A PRELIMINARY REPORT BASED ON FIFTY-EIGHT CASES.*

By

JOHN COWAN, R. CRUICKSHANK,
D. P. CUTHBERTSON, JOHN FLEMING,
AND A. W. HARRINGTON.

(*From the Royal Infirmary, Glasgow.*)

WHEN it was recognised that more than 90 per cent. of the cases of pneumonia were due to infection by the pneumococcus it was hoped that a specific antiserum might help in the treatment of the disease, but until recently the available sera have proved of little value.

Extensive investigations have thrown light upon the subject. Researches carried out in South Africa and in New York showed that there are several distinct serological types of pneumococci, and that antisera agglutinate their homologous strains and protect susceptible animals against infection by them. Three specific groups of pneumococci are recognised, Types I., II., and III. Strains which do not fall into these divisions are classed together in a heterogeneous group IV. or "x." Cooper and others have now shown that group "x" may be subdivided into a large number of specific types. To date some 22 different serological strains have been recognised.

Types I. and II. are responsible for 50–75 per cent. of the cases of pneumonia, but the exact proportion varies in different places at the same time, and at different seasons in the same place. Type III. is the least common but the most virulent; group "x" is more common and less virulent than III.; the virulence of I. is about the same as "x," while that of II. is intermediate between these and III.

The first requisite in the treatment of pneumonia by antiserum is the detection of the type of pneumococcus active in the particular case; the second is the supply of the corresponding antiserum, for it is useless to administer an antiserum which does not correspond to the active organism. At present effective antisera are only available for Types I. and II. pneumonias, but these infections constitute more than half the cases. The serum is antibacterial, not antitoxic—the pneumococcus has no demonstrable exo- or endo-toxin—and its function is to supply opsonins, agglutinins, precipitins, &c., which hasten the phagocytosis and destruction of the pneumococcus. It does *not* cause quicker resolution of the pathological lesions in the lungs, prevent death from cardiac failure or anoxæmia, neutralise non-specific poisons in the blood, or obviate the necessity for surgical interference in empyema.

The detection of the infecting type is a task which necessitates the loss of valuable time, typing from the sputum requiring nearly 24 hours, and from blood or lung cultures even longer. This is unfortunate, for the success of serum treatment is well known to depend upon *early* administration. Our practice, in consequence, has been to institute serum treatment as soon as the clinical diagnosis is made in *every* case of pneumonia, and to continue until the patient is better or we know that the type of organism is other than I. or II.

The series now recorded is too small for any definite conclusion as to the value of serum treatment in pneumonia to be reached, but in view of the importance of the subject we present our present figures for the consideration of the profession. Our results are gratifying in so far as they suggest that the use of serum has lessened, to an appreciable amount, the mortality of the disease in our practice, but too much must not be expected from serum treatment. Death, in pneumonia, may result from many causes, cardiac and respiratory failure, intoxications other than pneumococcal, or complications, side-issues of the infection, or the result of associated infections, or antecedent visceral disease. Against these the serum has no direct response.

We are indebted to the kindness of Dr. J. G. M. Bullowa, clinical professor of medicine in the University of New York, for our supply of Felton's serum, manufactured by the Lederle Antitoxin Laboratories; to the managers of the Royal Infirmary, and Dr. A. S. M. Macgregor and Dr. W. G. Clark, for their cordial coöperation in our work; and to the Scottish Branch of the British Red Cross Society for the financial arrangements. To all of these we offer our sincere thanks. We must also offer our thanks, for their personal assistance, to J. G. M. Bullowa, Isobel Brown, G. Cooper, L. D. Felton, Ian Grant, F. Griffith, J. S. Haldane, D. Ross, and Geoffrey Fleming; and to our wards Sisters, I. N. Prentice and E. Esplin.

Causes of Death in Pneumonia.

In pneumonia death may result from cardiac failure, anoxæmia, intoxications, or complications.

CARDIAC FAILURE.

The exact causes of cardiac failure are not yet accurately appreciated. It is true that granular, fatty, and hyaline changes are usually found post mortem in the myocardium, and that inflammatory changes are common. It is recognised that additional strain is thrown upon the right heart by the consolidation in the lungs, and that the blood pressure falls, sometimes to an extraordinary degree, during the course of the disease, but it is not clear how much of the circulatory difficulties are due to failure of the vis a tergo, and how much to disturbances in the peripheral circulation, from vaso-motor paresis. Both factors must be borne in mind. In any case it is essential to lessen the strain upon the heart from the commencement of the illness.

The chief indications are rest in bed and full nursing. Sleep is required, and there must be no

* The expenses of this mass test of Felton's serum have been borne by a grant from the Scottish Branch of the British Red Cross Society to the Royal Infirmary for the purposes of this investigation.

hesitation in securing it, if necessary, by the help of sedatives, of which we have found morphia given hypodermically the most helpful. It is true that its administration has been shown to lessen the respiratory rate to a slight extent (5 per cent.), and in consequence the oxygenation of the arterial blood, but this contra-indication is of less moment than the absence of rest and sleep, and can be remedied by the measures suggested for the treatment of anoxæmia. The occurrence of pleural pain is an additional indication.

Food, too, is essential and must be fluid. Diluted milk forms the staple, and readily digested carbohydrate (Horlick, Benger, &c.) can be added, or sugar in weak tea or coffee. Any distension of the abdomen must be remedied by alteration of the diet, and the use of rectal tube, enemata, and pituitrin.

Stimulants are generally required at some stage of the illness. Alcohol is said to be inert as a cardiac stimulant, but its effects in dilating the superficial vessels of the body and so increasing the heat loss, depressing the higher cerebral centres and so tending to ensure rest, and as a food which needs no digestion, are often useful. It should always be given to alcoholics. If the pulse lessens in rate and increases in value, if cold extremities tend to warm, if restlessness and delirium decrease, and the tongue becomes more moist, its administration is proving helpful (Murchison). The digitalis group are useful in moderate doses, and can be aided by caffeine and theobromine. Pituitrin should be exhibited if there are any suggestions of vaso-motor failure.

ANOXÆMIA.

The appearance of cyanosis is a clear indication of the presence of anoxæmia which occurs, to some extent, in every case of pneumonia. It is due to the lessened pulmonary area, the passage of blood through unaerated pulmonary capillaries, the lessened diffusion of gases from exudate in the pulmonary alveoli, and the shallow breathing which characterises pneumonia. It may be augmented in special cases by the existence of other pulmonary troubles such as bronchitis and pleural effusion. It has been shown by arterial puncture that anoxæmia may be extreme, the oxygen saturation being reduced to 60, 50, 40 per cent., or even lower, and that the administration of oxygen remedies the fault quickly and successfully. We have all seen such treatment remove, or at any rate lessen, cyanosis.

If the administration of oxygen remedies anoxæmia, anoxæmia should not be permitted to arise. In the past oxygen administration has been offered too late. Oxygen should be given in suitable amount continuously throughout the illness.

We have not had the opportunity of using an oxygen chamber. With it a concentration of 40-50 per cent. is used, generally the lower figure, with beneficial results. A concentration of 60 per cent. is deemed unsafe, but 40 per cent. has no ill-effect upon healthy persons sleeping under its influence. We have had to use other methods, Haldane's mask if possible, or the nasal tube. If these prove impracticable from delirium, &c., we exhibit oxygen freely through a funnel suspended above the patient's mouth. In consequence in this series cyanosis has rarely been severe.

THE INTOXICATIONS.

The intoxications of pneumonia are only in part due to the specific poisons of the pneumococcus, for it seems clear that anoxæmia and autolysis of the pulmonary lesions must interfere with normal metabolism. The prompt removal of these abnormal products is indicated and can be facilitated by increased elimination through the bowel, the skin and the kidneys. The first indication is the supply of sufficient fluid which may be given with the milk or separately as lemonade, soda water, &c. We have too, regularly administered potassium citrate (80–160 grains per diem) and liquor ammonii acetatis (4–8 drachms). The ammonia increases the formation of urea which acts as a diuretic, while the potassium salt also augments the urinary output, and, in addition, tends to increase the available alkali of the blood (Cushny).

It is impossible in this paper to discuss in full the vexed question of the acid-base balance in pneumonia. It has been known for long that in pneumonia there is as a rule a diminution of the CO_2 content of the arterial and the venous blood, though there is no appreciable lessening of the CO_2-combining powers of the blood. Various observers, using electrometric methods or indirect methods of measuring the pH of the blood, have concluded that it lies either within the somewhat discrepant range of normality or is definitely shifted towards the alkaline side. On the other hand, it has been repeatedly shown that the urine during the febrile stage of the disease is definitely acid, from an increased excretion of organic acids and acid salts. The ammonia output, too, is also increased.

In this series, in which alkalis were being exhibited, the reaction of the urine was noted accurately in 34 patients who recovered from the illness. The urine was alkaline to litmus before the termination of the fever in 9 cases on the day of termination of the fever in 6 cases; on the first day afterwards in 6 cases; on the second day in 4 cases on the third day in 4 cases; and subsequently in 5 cases. In 4 fatal cases the urine was alkaline before death.

On the available evidence we are inclined to trust the physiological evidence of the kidneys, which are clearly compensating an increased acidity of the tissues, rather than the evidence of the chemical examination of the blood. We continue the administration of the above-mentioned drugs for several days after the cessation of the fever, as it is known that the increased nitrogen output continues for several days after the fever has passed.

The Pneumococcal Intoxication.

On the admission of a patient blood is at once taken for culture and, immediately afterwards, a dose of 10,000 units of Types I. and II. serum is given intravenously. As a rule we have given a similar dose every eight hours until the fever fell below 102°, but we have not adhered strictly to this rule, giving more or less frequent doses according to the general condition of the patient rather than to the height of the fever. The signs of toxæmia, delirium, exhaustion, incontinence, &c., are more dependable criteria. In all we have given 348 doses to 58 patients, an average of 6, the extremes being 26 and 1.

We have not followed the bacteriological evidence as to type strictly, for we have found that the first examination of the sputum is not necessarily correct, presumably from contamination by bacteria derived from the mouth where, as is well known, pneumococci, most frequently group "x," are often present in healthy individuals. In one early case, which ultimately proved fatal, we unfortunately ceased administration of the serum on the sputum report of a group "x" infection, until the results of the blood culture proved that the infection was Type II. Cultures from the blood or lung are more likely to be accurate. Latterly we have continued the use of

serum in every case until satisfied by *repeated* examinations that the infection was *not* Type I. or II.

In 4 cases the sputum report was group "x," while blood culture showed Type I. in 2 cases, and Type II. in 2 cases. In 3 cases with negative blood cultures the first sputum reports were group "x," subsequent examinations showing Type I. in 1 case, and Type II. in 2 cases.

The administration of large doses of serum, intravenously, necessarily entails the risk of anaphylaxis, but the Felton serum is manufactured in such a way as to minimise this risk. It is derived from the serum protein of immunised horses by precipitation of the globulin antibody-carrying fraction in a large bulk of distilled water, the precipitate being redissolved in concentrated solution so that the therapeutic dose measures about 10 c.cm. A conjunctival test of sensitivity is made before the first injection.

In this series anaphylactic phenomena occurred in six cases. Immediate reactions occurred in two cases, succeeding the administration of the first dose. The patients became very short of breath and cyanosed, and the pulse failed, but these symptoms rapidly disappeared on the exhibition of adrenalin and atropine. In one case a second dose produced a similar but less severe reaction; the other patient did not require a second dose. In two cases urticarial eruptions were noticed a few hours after the first dose of serum. Late reactions occurred in two cases. In one patient who had had ten doses pyrexia, accompanied by arthritis, ensued on the twelfth day of illness and persisted for seven days. In the other case pyrexia, accompanied by inguinal adenitis, occurred on the fourteenth day of illness and persisted for eight days. This patient had had 11 doses, all given through the veins of the arms. Neither patient was acutely ill.

Discussion.

During the period of this investigation 60 cases of pneumonia were admitted into the wards. Of these, three patients were not given serum, for various reasons; they all made a good recovery. The other 57 patients were given serum. To these we have added another case, admitted in December, 1929, who received serum which had been presented to us by Dr. Bullowa. Of this series of 58 cases one patient (Type III.) died within 24 hours of admission. The others survived for at least 48 hours.

This series of cases is too small for any accurate conclusion as to the value of the treatment to be reached. We have no definite standard for comparison, but we show the results in an *untyped* series treated by us in the same wards during the last 20 years.

It is well known that the mortality of pneumonia varies considerably from year to year according to

TABLE I.—*Mortality per cent. in Pneumonia not Treated with Serum.*

	Osler.	Cecil.	Cole.	Bullowa.	Ferguson and Lovell.
Type I. ..	24·1	32·6	—	31·0	26
,, II. ..	37·7	54·6	—	30·0	20
,, III. ..	53·7	28·6	43·0	—	—
Group "x" ..	22·2	38·3	12·8	—	24·6

the character of the epidemic; and varies, too, with the age and sex and constitution of the patients. In our old series the males numbered 73·3 per cent., in the new series 65·5 per cent. In the old series the patients under 40 years of age numbered 76·2 per cent., in the new series 75·8 per cent.

The patients were not a picked group. Four showed a positive Wassermann reaction; one had aortic valvular disease, and one fibrillating auricles; one suffered from phthisis; two had chronic otitis media; one had rheumatoid arthritis; three were clearly chronic drunks. The virulence of the disease was at least of average severity. The fever lasted for eight days or more in 11 cases, and touched or exceeded 103° F. in 23 cases. The pulse-rate touched or exceeded 120 in 27 cases. The respirations numbered 40 or more in 33 cases. The blood pressure fell below 100 mm. Hg in 13 cases.

There is great difference in the mortality of the various types of pneumonia as shown by different observers in Table I.

Our own results are given in Table II.

TABLE II.

Males	.. 633	..... 127 (20·06)	38	..... 6 (15·7)
Females	.. 223	..... 31 (13·9)	20	 0

The reduction in the mortality is thus considerable.

The incidence of the different types of pneumococci in a series of cases in Glasgow during the year 1930 is shown in Table III.

	Total series.	Serum treated series only.
Type I...	.. 68	15
,, II...	.. 88	26
,, III...	.. 3	1
Group "x"	.. 41	13
	200	55

Felton's serum is only active against Types I. and II. infections; it has no therapeutic value in Type III. and group "x" infections. Of the 15 Type I. infections 1 patient died; of the 26 Type II. 2 patients; of the Type III. the only case; of the 13 group "x" infections 2 patients. Grouping the Type I. and II. infections together and contrasting the results in the other groups the figures are:—

Types I. and II. 41 cases .. 3 deaths .. mortality 7·3 per cent.
Other types .. 14 ,, .. 3 ,, .. ,, 21·4 ,,

We have not, as yet, any records of Type I. and II. infections treated in this country without the aid of Felton's serum, save those of Ferguson and Lovell, but the contrast between the gross mortality in our old and our new series, and the considerable difference between the mortality of the Types I. and II. cases, and the others (*upon which this serum has no effect*) in our new series, are sufficiently suggestive of the value of Dr. Felton's addition to our therapeutic armamentarium.

The difference in the mortality of pneumonia in America and at home requires investigation. Dr. Bullowa suggests that our patients come under treatment at an earlier stage

of the disease than is the case in New York. In this series the serum treatment of Types I. and II. infection was commenced, so far as we can ascertain, within 48 hours of the onset of the illness in 16 cases; within 72 hours in 7 cases; within 96 hours in 10 cases; within 120 hours in 6 cases; within 144 hours in 2 cases. Two of the Types I. and II. patients who died received serum within 48 hours of the onset and one within 72 hours.

A REPORT ON LOBAR PNEUMONIA: TREATMENT BY CONCENTRATED ANTISERUM

BY THE PHYSICIANS TO THE ROYAL INFIRMARY, EDINBURGH.

IN the latter part of 1929 a quantity of concentrated antipneumococcus serum was made available by the Medical Research Council for clinical trial in the Royal Infirmary.

In order to show that a remedy is of benefit in the treatment of lobar pneumonia, it would be necessary to demonstrate that it is capable of (*a*) reducing the case-mortality; (*b*) modifying the course of the disease; or (*c*) lessening the severity of the illness. For various reasons the matter is not as simple as it would appear at first sight. Effects on the case-mortality present special difficulty, since the death-rate in pneumonia may vary within wide limits not only in different places, but also in the same institution from year to year under apparently identical conditions. Deductions from small series of figures are always unsafe, and especially in such a subject as pneumonia, where the course of the disease is influenced by so many factors, such as the age of the patient, his previous health, habits, &c. The severity of the illness cannot be readily measured,[1] and experience shows that even those patients apparently extremely ill may recover without specific treatment.

Scheme of the Investigation.

At the outset of the investigation it was decided to give serum treatment without distinction to every alternate case of lobar pneumonia admitted to each of the eight medical charges in the Royal Infirmary. The remaining cases were to be treated in the usual way and were to serve as controls. This plan was carried out for about two and a half months and the cases belonging to this period are designated by the letter B. (before) in Table I. Later, owing to the small quantity of serum available, instructions were issued to choose the more seriously ill patients for treatment with the antiserum. The later cases are indicated by the letter A. (after). As has been pointed out, the subjects in the earlier period (B.) were quite unselected, so the serum and control cases are strictly comparable. In the second period the serum groups contain a larger proportion of the more seriously ill. The non-serum controls in this group (A.) include the less severe cases. Certain patients who were practically moribund when admitted to hospital were not given serum and are shown primarily amongst the controls.

In order that the serum cases and the controls should satisfy statistical requirements, the two groups should be of approximately equal size and as nearly similar as possible in such matters as the age of the patients (see Table III.), their physical state, the day on which they were admitted to hospital (Table IV.), &c. Owing to the selection of more severe cases for serum treatment during the second period, the non-serum cases in this group are not strictly comparable. The results obtained in the two periods (B. and A.) are so similar, however, that it would seem justifiable to group them together for purposes of analysis. This, of course, would tend to operate to the disadvantage of the serum results.

The concentrated antipneumococcal serum employed was that of Felton prepared by Messrs. Lederle of New York. It was active only against organisms of Types I. and II., and contained 10,000 units

each dose (5 c.cm.). As it has been shown that the earlier the serum can be administered the more favourable is the result likely to be, it was decided that the initial dose of serum should be given to the patients as soon as the diagnosis had been established and without waiting till typing of the organism had been completed. This resulted in a number of pneumonias of Types III. and IV. receiving one or more doses of serum before information regarding the type was available. This waste was more than outweighed by the advantage of being able to begin treatment earlier in the other cases. Table II. gives the number of doses received by patients in the different classes. Before serum was administered to a patient inquiry was made as to whether any

serum had previously been given, and the presence of undue sensitivity was sought by placing a drop of normal horse serum in the conjunctival sac. During the period covered by the inquiry 106 cases of lobar pneumonia came under review. For various reasons (e.g., absence of sputum) typing was not carried out in 17 of the subjects. The remaining 89 cases were distributed as follows : Type I., 29 ; Type II., 41 ; Type III., 2 ; and Type IV., 17. The serological type of the pneumococci present in the sputum was determined by the usual macroscopic agglutinate method after mouse inoculation. Details of the technique and an account of the type incidence in Edinburgh during the years 1929-30 are being published by J. M. Alston and D. Stewart.[2]

LUNG PUNCTURE.

In certain cases in this series—most frequently in those admitted at an early stage in their illness—no sputum could be obtained for several days and occasionally not until actually after the crisis. By puncture of the lung substance over the affected lobe it was found that in the majority of such cases a pure

culture of the pneumococcus could be obtained. The technique of this procedure and the results obtained have already been recorded.[3]

BLOOD CULTURE.

In 51 cases blood culture was performed. Ten cubic centimetres of whole blood was removed from the arm by venepuncture and was immediately transferred to flasks containing 50 c.cm. of phosphate broth (pH 7·6). The flasks were then incubated for 72 hours, being examined at daily intervals. A

positive result was recorded in 6 of the 51 cases, in each case a pure culture of pneumococcus being obtained corresponding in type to that found in the sputum. No growth of pneumococcus was noted in 45 cases.

The majority of the blood cultures were done in cases that were admitted early in the investigation,

and it is interesting to note that death occurred in all cases where a positive culture was obtained; while no patient who survived showed a positive blood culture.

Analysis of Results.

CASE MORTALITY.

A summary of the findings is given in Table I. The total figures are so small that it hardly seems justifiable to express the results as percentages. The distribution of the deaths, however, is striking. It will be observed that amongst the Type I. cases none of those who received serum died, while there were five deaths in the control group. Similarly amongst the Type II. pneumonias there were considerably fewer deaths in those treated with serum. At first sight this would appear to be convincing evidence in favour of the serum, but closer scrutiny modifies this view. It is well known that the death-rate in pneumonia increases with age, rising from about 5 per cent. under 20 years, to about 100 per cent. over age 70.[4] The serum cases and the controls are not closely similar in matter of age, since only the latter group contains subjects of 60 years and over (Table III.). In the first two groups all the patients of this age died with the exception of one. It will be noticed that though two cases of 60 years of age affected with pneumococcus of Type III. survived their illness, all the others of like age in Group IV. and in the untyped class ended fatally. In addition, it will be observed that several of the patients who did not receive serum died within a few hours of reaching hospital, two were moribund on admission, and others were extremely ill and may have been adversely affected by being moved to the infirmary late in the course of the disease. When consideration is given to these facts the smaller proportion of deaths amongst the serum cases would appear of less importance.

EFFECT OF SERUM TREATMENT ON THE COURSE OF THE DISEASE.

Duration of the fever.—As is well recognised, it is often difficult to ascertain exactly the day upon which the pneumonia commenced. A large proportion of the subjects in this investigation had suffered from some "cold" or catarrhal condition for a week to a month before the onset of symptoms which could be definitely recognised as pneumonia. The earliest signs of the major disease may either be those of an abrupt febrile invasion, or local symptoms referable to the chest. There is thus often an element of doubt as to the exact duration of the illness, but every effort has been made to minimise this. The day of the disease on which the patients of Groups I. and II. came under treatment is shown in Table V. It will be observed that the majority of the patients were not admitted to hospital until after the third day of their illness.

TABLE V.—*Fall of Temperature in Relation to First Dose of Serum.*

Interval to crisis.	Day of disease on which serum given.							Totals.
	1	2	3	4	5	6	Unc.	
1 day and under .	—	1	2	3	3	—	—	9
2 and 3 days ..	—	1	2	2	—	3	—	8
4 days and over..	1	1	2	1	1	—	1	7

A great deal of information regarding the duration of the febrile period in this disease is available as a standard for comparison. Many analyses have been published showing the proportion of cases which end by crisis on different days of the disease.[4] From these it is evident that, while in the majority of pneumonias the temperature begins to fall from the sixth to the eighth day, there are many which run a shorter course. The accompanying chart compiled from twelve series of records shows the percentage distribution of the crisis in 7442 cases together with the limits of the figures given by the individual observers (shaded area). Taking the records of all the pneumonias of Types I. and II. together and omitting the fatal cases, it is found that 24 were treated with serum and 26 are available as controls. The average age of the non-fatal serum cases is 33·8 and that of the surviving controls 32·0 years, so that the two groups are fairly comparable. When the duration of the illness is examined, there is at once apparent a very marked difference between the two groups, especially in the case of Type I. No less than 50 per cent. of the serum cases ended critically on or before the fifth day, while the corresponding figure for the controls is only 19·2 per cent. (The value for the 7442 cases mentioned above is 26·0 per cent.) When it is considered that the later serum cases include some of the more severely ill patients, and that eight of the patients did not commence treatment until the fifth day or later, the result is even more striking. Experience has shown that abortive forms of the disease occur more frequently amongst young individuals, cases of three or four days' duration being not uncommon amongst children. In order to give weight to this point, the ages of all patients under 15 years of age are shown in italics in Table I. It is probable that the figures for the control group gain advantage from the inclusion of two patients aged 11 who had a crisis on the third and the fourth day respectively. The accompanying chart shows the percentage distributions of the serum cases and the controls according to day of crisis. Each group includes a single third-day crisis—a proportion to be expected from the published tables. The values for the fourth and especially for the fifth day in the case of the serum group are greatly in excess of expectation, while the later values are necessarily low. In the case of the control series, the figures lie fairly close to the average values within the limits expected. Of the 50 non-fatal cases of Types I. and II. it is well to notice that 18 who received serum and 15 controls were admitted on or before the fourth day, 3 serum cases and 6 controls on the fifth day, and 3 serum cases and 5 controls after the fifth day (Table IV.). Though the lateness in beginning specific treatment in certain cases would affect the total number of early crises, the two groups are fairly similar as regards time of admission to hospital. From the evidence submitted, it would seem a fair deduction that the administration of serum has definitely shortened the febrile period of the disease in a considerable number of cases. Table IV. shows the number of days which elapsed from the time of giving the first dose of serum to the onset of the crisis. No less than 9 of the cases who were admitted up to the fifth day of the illness had a definite crisis within twenty-four hours (second day, 1 case; third day, 2 cases; fourth and fifth day, 3 each). On the other hand, early administration of the serum is not necessarily followed by abortion of the disease. For example, the patient (Case 2) who commenced treatment within 24 hours of the onset of his illness and received 12 doses of serum did not have his crisis until the sixth day.

EFFECT OF SERUM ON THE SEVERITY OF THE ILLNESS.

Height of the fever.—Thermal reactions following the administration of serum have been reported.[5] These have not been seen in this series of cases. In a number of instances the giving of serum has been followed by a slight temporary fall of temperature of one or two degrees, but variations of this magnitude are not uncommon during the course of pneumonia. One or two cases appear to have a pseudo-crisis, but where

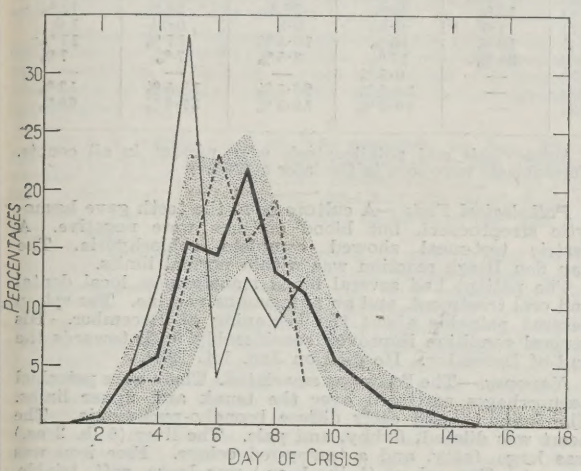

Chart shows the relative percentage distribution of the day of crisis in 7442 pneumonias which ended by crisis. The average values are shown by the heavy black line. The extreme limits given in the 12 different series from which the cases were drawn are shown by the shaded area. The control cases in this series (interrupted line) fall within expected limits. Serum cases (fine line) show a large percentage of crisis occurring on the fourth and fifth days of the disease.

a fall to normal occurred, the temperature usually remained down. In certain cases the impression was gathered that the serum, although it did not make the patient afebrile, kept the temperature at a lower level than is usual in pneumonia.[5] Except where a definite crisis occurred the pulse-rate and respirations were not usually influenced by the giving of serum. The temperature-reducing effects of the serum appear to be more marked in cases of Type I. than in those of Type II.

Leucocytosis.—In a number of cases observations in the leucocyte count were made daily. The usual reaction appeared to be a fall in the number of leucocytes, roughly in proportion to the change in temperature; an increase in white cells was only found in one patient

Blood pressure.—No striking change in systolic readings was observed.

There is no doubt in the minds of those who were watching the patients that the antiserum was of considerable benefit in certain cases even although the course of the illness was not shortened. Many of the patients appeared to have improved rapidly, becoming more comfortable and less distressed shortly after the serum had been given. (See Case 2.) Clinical histories of cases illustrating some of the more striking results are given below.

Illustrative Cases.

CASE 1.—Youth aged 18. Gave a history of "cold, cough," not feeling well," for seven days before admission. Continued at work till two days before admission. Pain in left side of chest, cough worse, vomiting, headache two days before admission; and spitting of blood one day before admission. Examination: Consolidation of the left lower lobe; well nourished; development good; acutely ill but no marked distress; temperature 102°, pulse 120, respiration 20–30. Blood culture—negative (twice). Sputum and lung puncture gave culture of pneumococcus I. Progress: Given one dose of serum on admission, at 8.45 P.M., on the third day of the disease. Conjunctival test negative. Following the injection the patient had a serum reaction like asthma, with urgent dyspnœa, cyanosis, and pain in the chest. One cubic centimetre of adrenalin eased the symptoms immediately. This injection was followed by a fall in temperature of 1° with consequent rise of 1·5° after six hours. Eighteen hours after admission there was sudden rise of temperature to 104·8° and he was given a second dose of serum. No anaphylactic phenomena followed this injection. After this the temperature came down steadily to normal, within 24 hours of admission and six hours after the second dose of serum. The fall in temperature was accompanied by all the typical signs of crisis. A very definite change was noted within a few hours of giving the second dose, not only in the temperature but also in the clinical condition of the patient. The ward sister, especially who has had considerable experience in nursing pneumonia patients, was impressed by the immediate improvement.

A similar asthmatic attack occurred in one other patient who had previously suffered much from bronchitis. He had never had asthma, and the preliminary eye test was negative.

CASE 2.—A man, aged 28, had had pain in left side of chest for one day before admission with slight cough, and shivering. He was admitted on the second day of illness. Examination: Consolidation of the left lower lobe. Patient extremely ill; collapsed; cyanosis marked. Temperature 101–103°; pulse 130–140; respiration 40–50. Blood culture negative (three times). Sputum, pneumococcus II. Progress: This patient was admitted within 24 hours of the onset of the illness, in a very critical condition. The prognosis was noted at the time as "almost hopeless." The white blood count was low, 8000. In all he received 12 doses of serum, injections being repeated every six or eight hours for five days. During that time "life hung in the balance." By the sixth day, however, definite signs of improvement were noticed, and by the seventh day it was obvious that the patient was going to live, all signs of crisis being present.

It is interesting to note that there was a gradual fall, both in pulse-rate and in respiration-rate, from the first dose of serum, although the patient did not seem to be making much headway. The ward sister, who also has had large experience in the nursing of pneumonia patients, attributed the recovery to serum. After the third and fourth doses of serum both doctors and nurses clearly noticed signs of improvement—less restlessness leading to natural sleep, less apathy, more coherent speech, sweating, and increased quantity of urine.

CASE 3.—A man, aged 39, had pain in the left side, with cough and insomnia for three to four days before admission. Examination: Consolidation of the left lower lobe. Blood culture negative. Sputum, pneumococcus I. White blood count 9000. Temperature 103°; pulse 100; respirations 40–50. Progress: This patient was chosen as a serum case because of the severity of his condition. Admitted on the fourth day, he was collapsed, cyanosed, and ashen-grey in colour—in short, extremely ill. He received one dose of serum two hours after admission, and within four hours his temperature had fallen to 99·5°. In another eight hours it had fallen to 97° F. A second dose was given 18 hours after admission, but by this time—that is, before the end of the fourth day—the crisis had occurred.

CASE 4.—Boy, aged 16, was feverish, with vomiting six days before admission; on the next day he had cough and pain and on the third day rusty sputum. Admitted on fifth day. Examination: Consolidation of right lower lobe. Well-nourished adolescent; no marked distress but severely ill. Temperature 103°; pulse 120; respirations 30. Blood culture negative; sputum, pneumococcus II. Progress: Admitted on the fifth day, one dose of serum was given at once. This was followed by a fall in temperature of 2°. A second dose of serum four hours afterwards was followed by relief, and by a fall of temperature to normal. A slight rise of temperature to 101° occurred eight hours afterwards, and a complete crisis took place 12 hours later. The recovery was uneventful.

CASE 5.—Man aged 30. Pain and cough for two days before admission; vomiting and rusty sputum for one day. The patient was moderately alcoholic. Examination: Consolidation of the left lower lobe; nutrition and development good; cyanosis; marked dyspnœa. Blood culture negative (twice), sputum, pneumococcus II. Progress: Reaching hospital on the third day of his illness, the patient was given a dose of serum, followed by further three doses at four-hourly intervals. Crisis occurred within 24 hours, with very marked improvement in general condition.

CASE 6.—Man aged 45. Indefinite "flu" 14 days before admission. Severe pain and vomiting three days before

admission, and headache; weakness two days. Examination: Consolidation of the right lower lobe; thin; nutrition poor; marked cyanosis; very marked distress; painful cough; rusty sputum; drowsiness marked. Temperature 104°; pulse 130; respirations 30–40. Blood culture negative (twice). Sputum, pneumococcus II. Progress: When admitted to hospital on the third day of the disease patient was in a collapsed condition. Three injections of serum were given within 24 hours followed by very marked improvement, and crisis occurred by the fifth day of the illness.

Summary.

The evidence submitted suggests that the administration of Felton's concentrated antiserum is of distinct benefit in the treatment of lobar pneumonia due to organisms of Types I. and II. Its action appears to be greater in the case of Type I. pneumonias. The records show that there were fewer deaths amongst the cases who received serum. Serum treatment seems to lessen the severity of the disease and undoubtedly shortens the febrile period in a proportion of cases. Many cases appeared to become less ill and more comfortable as a result of the injections. Anaphylactic phenomena were observed in two patients after the first dose of serum, although in both cases the preliminary eye test was negative. It is probable that the beneficial results would have been more striking had it been possible to commence treatment at an earlier stage in the disease, and if the supply of serum had permitted more frequent injections.

The writers wish to acknowledge their indebtedness to Dr. J. M. Alston and Dr. Donald Stewart and to Prof. Stanley Davidson for help in carrying out the investigations.

THE INFECTIVE FACTOR IN THE CAUSATION OF ACUTE MYELOGENOUS LEUKÆMIA.

BY J. H. EASTON, M.B. CAMB., M.R.C.P. LOND.,
MEDICAL REGISTRAR TO KING'S COLLEGE HOSPITAL.

THE following observations on three cases of acute myelogenous leukæmia lend support to the opinion of Dr. F. J. Poynton and Dr. A. A. Moncrieff [1] that the tissues, and the blood-forming organs in particular, are capable of reacting to infective processes in a great variety of ways and in varying degrees. The main features of these cases are an intensely severe sepsis in the mouth, associated with a marked and increasing secondary anæmia, and a white count in the early stages showing a leucopenia affecting the granular cells, followed by the appearance of a leukæmic blood picture of myelogenous type.

CASE 1, a male aged 19, was admitted to hospital on Nov. 12th, 1928, with a history of increasing weakness, giddiness, and headaches, following the lancing of an "abscess in the mouth" two months previously. A severe epistaxis necessitated his admission for blood transfusion. There was nothing of importance in his previous history; he was an average, healthy male.

He was markedly pale, with the right side of his face (around the mouth) puffy and swollen; he had difficulty in opening the mouth. There was a high temperature of swinging type (103°–100°), a pulse-rate of 120, and a respiration-rate of 30. There was a severe ulcerative condition of the mouth; the gums were swollen and œdematous, and oozed blood-stained muco-pus. The cervical glands were enlarged and tender. The heart was dilated, and an apical systolic murmur was present. The spleen and liver were not palpable. There were a few scattered petechiæ over the trunk.

(2)	800	27,200	66 400	24,000	10,600
(3)	15%	36%	28%	30%	18%
(4)	1·0	0·85	0·8	0·74	1·0
(5)	18%	18%	10·5%	17%	11%
(6)	82%	17%	3·5%	7%	7%
(7)	—	0·5%	—	—	—
(8)	—	35·5%	26·5%	18·5%	13%
(9)	—	29·0%	59·5%	57·5%	69%

Anisocytosis and poikilocytosis were present in all counts. Normoblasts were seen in the later counts.

Pathological Tests.—A culture from the teeth gave hæmolytic streptococci, but blood cultures were negative. A gastric test-meal showed complete achlorhydria. The van den Bergh reaction was within normal limits.

The patient had several blood transfusions, local dental and oral treatment, and an autogenous vaccine. The spleen became palpable about the beginning of December. His general condition improved considerably until towards the end of December. He died on Jan. 1st, 1929.

Necropsy.—The body was emaciated. There were petechial hæmorrhages scattered over the trunk and upper limbs. The lungs showed early diffuse broncho-pneumonia. The heart was dilated, flabby, and pale. The liver (5 lb. 2 oz.) was large, fatty, and a tawny-red colour. Free iron was present. The spleen (1 lb. 1 oz.) was large, soft, friable, and purple. The swollen pulp obscured the trabeculæ. The marrow of the sternum was a muddy grey colour; that of the tibia was reddish-grey.

Microscopical Appearances.—The spleen and the marrow from the long bones showed extensive myeloid hyperplasia. Many normoblasts were present in the marrow. Section of the liver showed severe fatty change around the portal radicles. Collections of immature myeloid cells were numerous in the portal spaces.

CASE 2, a female aged 28, was admitted to hospital on March 1st, 1929, with a four months' history of increasing lassitude and giddiness. Her teeth had been bad for some time, but her doctor told her that nothing could be done till she was stronger. A fortnight before admission she developed an acute feverish illness, which was associated with a sore-throat and swollen face.

Her appearance bore a striking resemblance to that of the previous case. The temperature was 103° and swinging in type, the pulse-rate 140, and the respiration-rate 30. Pallor was marked, and her face was so swollen around the mouth that the latter could only be opened with difficulty. There was noticeable fœtor of the breath. The gums were swollen and œdematous and almost completely obscured the teeth. The discharge from the gums was serous rather than purulent. Severe stomatitis was present. The cervical glands were enlarged and tender. The heart was not noticeably enlarged; the sounds were feeble and tic-tac in character. Bronchitis was present. The spleen was palpable one inch below the costal margin and was rather soft.

Blood Counts.

—	March 1st.	March 22nd.
Red cells	1,408,000	884,000
White cells	5,200	19,800
Hæmoglobin	32%	19%
Colour-index	1·1	1·12
Polymorphonuclear cells	54%	57%
Lymphocytes	43%	18·5%
Large mononuclear cells	3%	0·5%
Myelocytes	—	4%
Leucoblasts	—	20%

Anisocytosis and poikilocytosis were present in both counts. There were 140 normoblasts per c.mm. in the first count.

Pathological Findings.—A culture from the teeth yielded hæmolytic streptococci, but the blood culture was negative, the van den Bergh reaction normal.

In spite of rigorous local treatment and repeated mercurochrome injections intravenously, the patient went downhill

and died 21 days after admission. The spleen became impalpable towards the end.

Necropsy.—The body was emaciated. There were raw ulcers on the sides and roof of the mouth, with adherent sloughs. There was severe necrosis of the maxilla and the sides of the body of the mandible. There was a diffuse bronchitis, and bronchiolitis and the lungs were congested and œdematous. The heart was pale and flabby. The liver (3 lb. 11 oz.) was fatty and brownish-yellow in colour, interspersed with small discrete yellowish areas. The spleen (7 oz.) was rather soft, but the pulp was not noticeably swollen and the trabeculæ were easily made out. There were three dark purplish areas about the size of a halfpenny in the splenic substance. The marrow of the ribs was dry and yellow; that of the sternum and tibia was greyish-red.

Microscopical Appearances.—Section of the spleen showed little evidence of myeloid hyperplasia; the reticular structure was prominent. The liver showed collections of immature white cells of myeloid type. The marrow showed myeloid hyperplasia.

CASE 3, a female aged 59, was admitted on Jan. 30th, 1929, with severe epistaxis and nasal obstruction. Three months previously she had had similar bleeding from the nose, which had to be plugged. She had lost much weight recently. There were no important features in her past or family history.

She was noticeably pale and looked ill, with obvious nasal obstruction. She had a well-marked saddle-shaped nose (an appearance which she said had been present for 30 years). The temperature varied between 100·5° and 98°, and was of swinging character; the pulse-rate was 100, and the respiration-rate 22. Breathing was entirely through the mouth. Fœtor of the breath was noticeable. Her few remaining teeth were septic. There was an old perforation of the palate. The tongue was furred, and numerous ulcers covered its surface. The anterior pillar of the fauces, the tonsils, and the posterior pharyngeal wall were red and œdematous, with adherent greyish sloughs in places. The heart was dilated, and a systolic murmur of relative mitral incompetence was present. The spleen was palpable, one and a half inches below the costal margin, of firm consistency. The liver was felt one inch below the costal margin and was firm, with smooth surface and sharp edge. There were a few shotty glands in the groin. The tonsillar glands were enlarged. There were no abnormal signs in the nervous system save a bilateral eighth-nerve deafness. The urine had a specific gravity of 1020; a trace of albumin was present but no casts. Numerous petechiæ were seen scattered over the trunk and lower limbs. The Wassermann reaction was doubtful.

On Feb. 11th numerous red patches appeared on her arms and face; these varied in size from that of a pea to large areas, some three inches in diameter. They were raised above the skin surface with definite edge, and were of firmer consistency than normal skin. By Feb. 22nd the whole of the extensor surfaces of both arms and hands were covered by this infiltrative, hæmorrhagic, sharply marginated eruption. The upper parts of the face, the nose, the eyebrows, and the skin up to the roots of the hairy scalp in the frontal region showed a similar but less marginated rash. Both epitrochlear glands were palpable at this stage. During this time the throat condition had improved considerably under treatment. On March 1st the leukæmic infiltrations had begun to disappear, leaving a bruised appearance with surface desquamation. The spleen had not altered in size or consistency. The patient was obviously going downhill rapidly. Unfortunately her relatives took her out of hospital on March 22nd and she was lost sight of.

Blood Counts.

DISCUSSION.

It is hard to believe that a clinical picture such as has just been described could be produced by the lowering of the patient's resistance by a process which affects the blood-forming organs and of the nature of which we are completely ignorant. We must, therefore, be drawn to the conclusion that infection is the essential cause. We are not concerned here with any specific factor; my intention is merely to put forward the theory that the blood-picture in many cases of acute myelogenous leukæmia is a special response of the hæmatopoietic system to a virulent infection.

The process seems to be evolved in this way. The organism gains an entrance to the body, commonly at the site of septic tonsils or teeth, and sets up a severe local inflammatory reaction. The patient is ill, with high swinging temperature, tachycardia, toxic appearance, and perhaps a purpuric rash. In certain cases at first the blood-forming tissues are paralysed, and the individual puts up no resistance. At this stage examination of the blood shows a profound secondary anæmia and marked leucopenia. Many cases are reported in which death has occurred at this point and in which the diagnosis has been "agranulocytic angina," "aleukæmic leukæmia," or "aplastic anæmia," diagnoses which depend on certain small characteristics of the blood picture. If the infection is resisted successfully, the blood-forming organs work hard to overcome it. A blood examination will show evidence of marked activity, with the presence of normoblasts, myelocytes, and myeloblasts. The liver, spleen, and marrow would show evidence of hyperplasia on the part of the reticulo-endothelial cells. There is a striking similarity, surely, between this picture and that of the response to the ordinary pyogenic infection, the only difference being in the actual degree of activity of the hæmatopoietic system. In certain cases of virulent infection with hæmolytic streptococci, for example, there is the same leucopenia in the initial stages, and death may occur. In a favourable case, however, a polymorphonuclear leucocytosis appears and the patient recovers.

It is obvious that there are two factors in the matter: one is the virulence of the organism, the other is the state of the individual's resistance. I would suggest that in cases of acute leukæmia the infection is a virulent one—in two cases hæmolytic streptococci were isolated—and that the individual has strong powers of resistance to begin with, but that it is in the great majority of cases overcome in the end. The fact that it commonly attacks healthy young adult males would support this. That every case of acute leukæmia is due to an infection is very difficult to imagine, far more so to prove, but I suggest that this causation is more frequent than is generally supposed. A recent review of the literature by Warren [2] goes far to support this. Experimental evidence has so far been conflicting. Several classical cases of the transference of the disease have been reported, but conclusive evidence is still wanting.

One conclusion certainly emerges from a study of these cases: that though our knowledge is still far from complete, there is great need for a restatement of our ideas on blood diseases in general with special reference to those directly due to infection.

I am indebted to Dr. A. C. D. Firth and Dr. C. F. T. East for permission to publish their cases.

[2] Warren, S. L.: Amer. Jour. Med. Sci., 1929, clxxviii., 490.

MOTOR LICENCE OF EPILEPTIC DRIVER.—Under the new Road Traffic Act, the Manchester Watch Committee have decided to revoke the driving licence of a private motorist reported to be an epileptic. It was stated that the driver was involved in an accident due to an attack of epilepsy.

CLINICAL AND LABORATORY NOTES

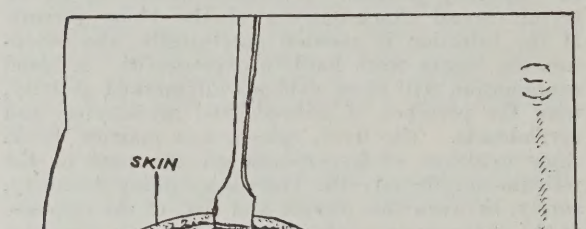
ON APPROACHING THE APPENDIX THROUGH A TRANSVERSE INCISION.

By A. J. Cokkinis, F.R.C.S. Eng.,
SURGICAL REGISTRAR, ST. MARY'S HOSPITAL.

For some years I have employed in certain cases of appendicitis an operative approach which may be worthy of publication. Its originality cannot be vouched for, but it is not described in the standard text-books and I have not encountered it in the somewhat limited research which I have made into the vast literature on the subject.

The approach is equally suitable for acute and chronic cases, and can be employed for the drainage

Fig. 1.



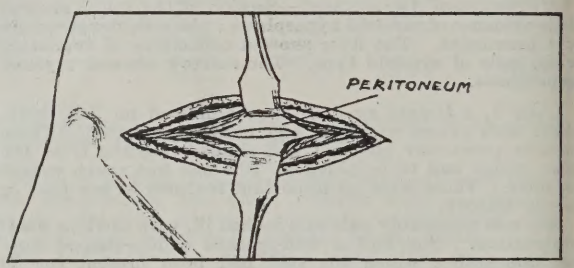
of an iliac abscess as well as for the removal of the appendix. It has, however, one important limitation—i.e., the incision is horizontal and cannot be prolonged to deal with an epigastric or a low pelvic lesion. When the diagnosis of an iliac appendix is reasonably certain, and a general exploration of the abdomen is either unnecessary or undesirable (very frequently the case in these days of improved diagnosis and conservative surgery), this method has very real advantages. It provides an excellent approach, permits of a rapid and easy resection of the appendix, and has proved the simplest and safest route for a retroperitoneal approach and the drainage of an iliac appendix abscess. Other advantages will be pointed out later.

TECHNIQUE.

For appendicitis without abscess.—The incision is absolutely horizontal, and extends from the anterior superior iliac spine inwards for 1½ to 3 inches, according to the age and build of the patient. The external oblique aponeurosis is exposed and a few of its muscle-fibres will be seen at the outer end of the wound. One or two bleeding-points may require ligature. The aponeurosis is split in the line of the skin incision and the muscular fibres of the internal oblique are exposed. These fibres are here running almost transversely and a line of separation is made with a blunt instrument. The transversalis is then split in a similar manner and the transversalis fascia divided in the same direction. One nerve only is likely to be encountered; this is the iliohypogastric, which pierces the internal oblique an inch or so in front of the anterior superior spine and can be readily displaced.

The peritoneum is now exposed, and at the outer angle of the wound this can be seen coming off the

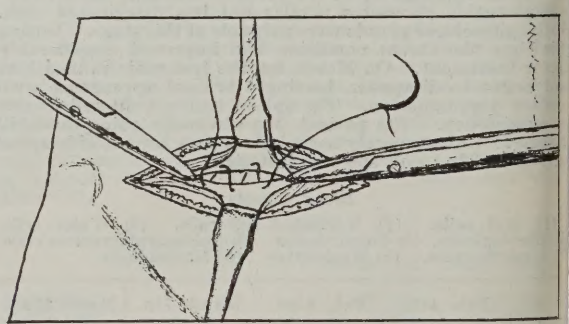
Fig. 2.



iliac fossa to the anterior abdominal wall in the form of a lateral reflection, which stands out as a definite fold. It is picked up and incised horizontally, a 1½-inch opening usually being sufficient. The cæcum will be found immediately under the wound and can be delivered very easily, except when anchored by adhesions. An adherent subcæcal, retrocæcal, retrocolic, or ileal appendix can be freed and brought out with greater ease than through the more medial oblique or vertical incisions in common use. These four positions between them account for no less than 68 per cent. of 5000 cases investigated by Wakeley and Gladstone.[1] Real difficulty has only been encountered in appendices bound down in the pelvis, and even here the procedure can be greatly facilitated by prolonging the incision inwards for half an inch or an inch.

After the appendix has been amputated and the stump invaginated, the edges of the peritoneum can

Fig. 3.



be picked up with great ease and brought together with a suture. I frequently employ a single running suture puckering the peritoneum, one knot being sufficient. The muscle-fibres are approximated with one mattress suture, the aponeurosis sewn up, and the skin wound closed, preferably with a subcuticular suture.

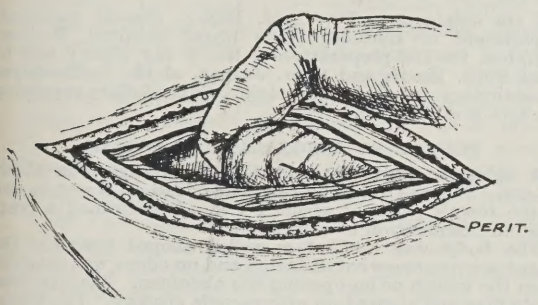
For iliac appendix abscess.—In the presence of a localised abscess, shut off from the general peritonea

[1] The Lancet, 1928, i., 178.

cavity, modern teaching favours conservative methods. The immediate indication is to open and drain the abscess, and only to remove the appendix when this can be done without danger of infecting the peritoneum. Appendicectomy can be performed in other cases at a later date, with incomparably greater safety. A pelvic abscess should be opened through the rectum, but in the case of an iliac abscess the ordinary transperitoneal approach must be condemned, as it entails a definite risk of peritoneal infection.

My approach provides a safe route for the evacuation and drainage of an iliac abscess, as the entire procedure can be carried out extraperitoneally. The incision need only extend for 1½ to 2 inches inwards from the anterior superior spine. After the aponeurosis has been divided and the muscles

FIG. 4.



Perit. = peritoneum peeled off iliac fossa.

split, the reflection of peritoneum coming off the iliac fossa is sought and peeled inwards off the iliacus until the abscess can be felt from behind. It is then opened with the finger or with sinus forceps and cleaned out with swabs on holders. A drainage-tube is inserted into the abscess cavity and brought out through the outer end of the wound. With the patient lying a little over on the right side very excellent drainage is provided. In this way all danger of soiling the peritoneum is avoided, and in every case in which this technique was followed the result was satisfactory, the abscess clearing up and the wound usually healing in less than half the time required for the healing of an abscess opened transperitoneally.

ADVANTAGES.

(1) This method provides the easiest possible approach to the cæcum and therefore to the appendix, when this is not bound down in the pelvis. With the incisions in common use several minutes may be spent in pulling out coils of ileum before finding the cecum. (2) It causes less damage to the abdominal wall, as no nerves get in the way, and the muscles are split in the direction of their fibres. As a result, the danger of ventral hernia is greatly reduced. (3) It has this great advantage over the grid-iron incision: all the layers of the abdominal wall are split in the same direction and, therefore, a greatly improved exposure is obtained. (4) The horizontal incision lies in a natural fold; the scar cannot stretch and becomes practically invisible. (5) With little experience, considerable time is gained over other methods; in uncomplicated cases the operation could be completed in 7 to 10 minutes. (6) Its advantages in the treatment of an iliac abscess are very real and perhaps constitute its greatest recommendation.

To sum up, this approach is confidently recommended as worthy of trial in cases in which the diagnosis of an iliac appendix is clinically certain, and particularly when an iliac abscess is suspected. I have employed it in over 200 cases, and in only five of these was it necessary to make a fresh incision to deal with some other abdominal or pelvic lesion.

TWO UNUSUAL CASES OF SUICIDE.

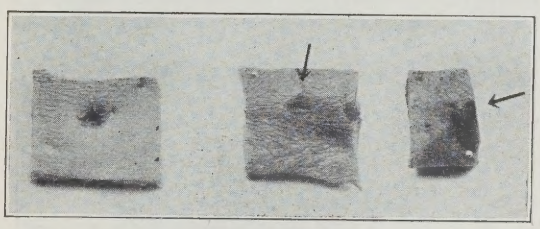
BY W. STEWART, M.B. GLASG.,
ASSISTANT PATHOLOGIST, THE ROYAL HOSPITAL, WOLVERHAMPTON.

TWO GUNSHOT WOUNDS IN THE HEAD.

Two brothers were in partnership as dairymen. On the morning of the occurrence both brothers got out of bed at the same time, about 6 A.M. One went out to bring in some cattle, while the other (the deceased) went about the household duties he usually performed. The one who had gone out returned within half an hour to find his brother lying unconscious in the back kitchen. He noticed some hæmorrhage from the forehead. He summoned assistance, and while attending to his brother found a rifle underneath his body. The doctor who was called in washed and bound up the wounds and sent him into hospital, where he died some three hours later without regaining consciousness. The doctor afterwards stated that there was no tattooing from gunpowder around either of the wounds before he had dressed them.

The *post-mortem examination* was performed on the following day. There were two punctured wounds in the

FIGS. 1 2 3



Entry wounds of bullets: 1. Fired into dead skin at distance of three feet. 2. Fired into dead skin at distance of one-tenth inch. 3. Skin from Case 1.

forehead, both measuring in diameter three-sixteenths of an inch. One was situated in the mid-line, two inches above the bridge of the nose, and the other in the upper margin of the right eyebrow in a line with the outer angle of the right eye. There was no burning or scorching around either of the wounds, nor was there any singeing of the eyebrow. The wound in the middle of the forehead penetrated the whole depth of the tissues, and at its base, lying against the bone, was found a flattened bullet. There was no injury to the bone at this point. The other wound, over the right eye, penetrated the skull. The bullet had made its way diagonally across the brain and in a slightly downward direction. It was found in the brain substance at the tip of the left occipital lobe. There was no injury to the base of the skull.

There was no organic disease of the brain. The examination of the other internal organs showed only slight tuberculous infection of the apex of the right lung.

On first thoughts this would seem to be a case of homicide. Would it be possible for deceased to have fired both shots? There was no known motive for suicide; the deceased was not embarrassed in any way.

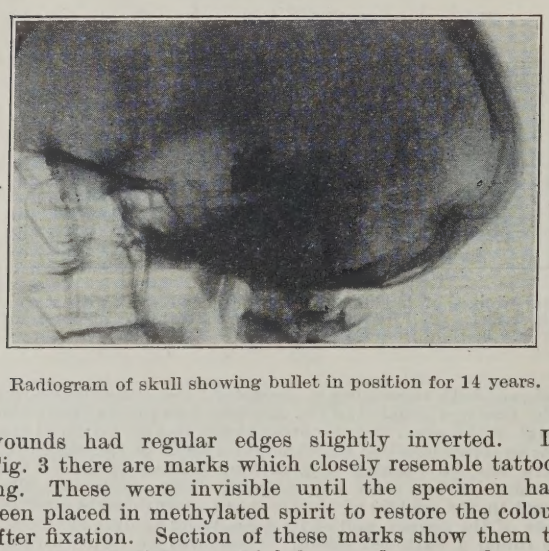
The rifle was a Marlin repeating rifle, calibre 0·22. It had a tube beneath the barrel capable of holding, I think, 15 cartridges. After firing a lever is pushed

down and is then brought back to its original position by closing the hand. This procedure automatically ejects the spent cartridge, cocks the rifle, and reloads. It could also be used as a single-shot rifle, but in any case the lever has to be used. The bullets were "long but short," and the powder smokeless. They were of American type and of old manufacture. If the deceased did fire both shots it was only possible for him to do so at very short range. There were no contrivances for pulling the trigger, and he was wearing his boots.

The classical signs of a near gunshot wound made by similar bullets may be taken to be: (1) burning and singeing round and near the wound, accompanied by some bruising; (2) tattooing due to deposit of unexpended gunpowder. All these were absent in this case, except some slight bruising in the lower border of each wound.

With the assistance of the police some experiments were carried out with the rifle in question, using similar cartridges. With a piece of cardboard there was distinct evidence of tattooing up to a distance of 18 inches. Burning and scorching were difficult to assess owing to the composition of the target. The experiments were repeated, using material from a post-mortem examination, the results being shown in the accompanying photograph. Fig. 1 shows a shot fired at a distance of 3 feet; it shows distinctly irregularity of the edges. Fig. 2 is of a shot fired at as short a distance as was compatible with safety during the experiment, approximately a tenth of an inch. It shows absence of scorching and singeing. Fig. 3 is that of the deceased. Both of the deceased's

FIG. 4.



Radiogram of skull showing bullet in position for 14 years.

wounds had regular edges slightly inverted. In Fig. 3 there are marks which closely resemble tattooing. These were invisible until the specimen had been placed in methylated spirit to restore the colour after fixation. Section of these marks show them to be subepithelial petechial hæmorrhages; there is no destruction of the squamous epithelium. The hæmorrhages were confined to the subcutaneous areolar tissues.

These experiments showed quite clearly that the rifle had been fired at very close range, although practically all the signs of close-range firing were absent. It is probable that of the two shots the one in the middle of the forehead was the first to be fired. One would have thought that the deceased, having received the first shot, would have been too much incapacitated from shock to fire a second shot within such a short interval. That shock is not commonly present in gunshot wounds was shown by the late Sir Frederick Treves from experience gained during the South African War.[1] Numerous cases could be quoted from the late war—for example, the X ray photograph (Fig. 4) showing a bullet lodged in the right temporo-sphenoidal lobe. The recipient received it from Turkish rifle fire near Kut on May 1st, 1916. He states that he had no idea he had been wounded, his only symptom being a slight trickle of blood down his right cheek, and he walked, without assistance, a distance of one and a half miles to a dressing station. The bullet penetrated over the right eyelid in much the same position as in that of the deceased. At present his only symptom is very slight loss of memory. All honour to the surgeon who left the bullet alone!

Although there was no tattooing around the wounds of the deceased, microscopic section showed abundant deposit of unspent gunpowder in the deeper layers of the tissues.

The jury returned a verdict of "Suicide during temporary insanity."

I am indebted to Dr. C. M. Rigby, clinical assistant, Department of Radiology, the Royal Hospital, Wolverhampton, for the preparation of the X ray plate; and to Chief Supt. Heath and Supt. Jeffery, of the Staffordshire Constabulary, for their coöperation, Supt. Jeffery supplying the details of the rifle.

SUICIDE BY BINOXALATE OF POTASH.

A spinster, aged 37, arrived in Wolverhampton about 10 A.M. She was found by the police dead on a seat in one of the town's parks at about 1 P.M. I performed a post-mortem examination two days later.

The body was that of a well-developed female; the features were somewhat distorted and no odour was detected from the mouth or on opening the abdomen. The liver was fairly firm and showed no macroscopic changes. The spleen was soft and friable. There were no signs of corrosion of the mouth; the œsophagus was grey in colour, and there was no destruction of the mucosa. The stomach contained four ounces of a dark-brownish blood-stained material. The internal wall was wrinkled and whitish-grey, and the congested vessels were sharply demarcated from the surrounding tissues as blackish arborescent streaks. In one place there was evidence of a healed ulcer. The small intestine showed similar congestion down to a few inches above the ileo-cæcal valve, the appearances of the vessels being somewhat similar to those of the stomach, although not so pronounced. The mesenteric glands were tuberculous, and some were calcified. Both Fallopian tubes showed tuberculous invasion, and the tip of the appendix was adherent to the right ovary, which was cystic. The uterus showed some endometritis. The heart showed no abnormality. The lungs were congested, and for a radius of about two inches around the hilum the blood was a bright red. The pancreas and the kidneys showed venous engorgement.

Microscopic examination of the latter showed that the glomeruli had almost all escaped damage; in only a few was there a slight hæmorrhage, with no degenerative changes. There was extreme degeneration in the tubules, the collecting tubules being the least affected; there was also considerable interstitial hæmorrhage. The brain was somewhat congested, and showed towards the base a few petechial hæmorrhages.

About fifty yards from the body were found a labelless four-ounce bottle and a small tumbler containing a white crystalline substance, which afterwards proved to be binoxalate of potash. I was able to find grs. 31·34 of this substance in the stomach contents alone. The deceased had previously vomited; the vomit I did not obtain. A solution made from the teeth, which were false, also gave a typical reaction. This was interesting, since one of the reactions is a white precipitate with silver nitrate and the normal contents of the stomach also give this white precipitate. On allowing the filtered gastric contents to crystallise out, only a few rhombic prisms were obtained, the majority assuming the plumose shape.

I am indebted to Dr. S. C. Dyke, consulting pathologist to the Royal Hospital, for permission to record these cases.

MEDICAL SOCIETIES

CHELSEA CLINICAL SOCIETY.

Dr. F. J. McCANN took the chair at a dinner meeting of this Society held at the Rembrandt Rooms on Dec. 16th, when a discussion on

Fibrositis

was opened by Sir THOMAS HORDER.

The treatment of all fibrositic conditions, he said, from the simple attack of lumbago to the many involved and obscure forms now recognised, depended largely on a correct appreciation of the numerous ætiological factors involved. The chief of these were: (1) microbic infection, which had hardly been mentioned 20 years ago and would perhaps be almost forgotten 20 years hence, and which to-day was somewhat overrated; (2) metabolic defects, such as the oxalic and possibly the phosphatic diathesis; (3) defective nutrition, including that seen in patients who had been treated by means of ill-conceived dietetic methods; this included the plethoric condition, of which the "city alderman" was an example. The factors outside the physician's control were also important: (4) age, (5) sex, (6) heredity, (7) the menopause, (8) climate, (9) occupation, and (10) trauma.

The view that microbic infection was the dominant factor was so strong to-day that in most text-books the term "rheumatoid arthritis" had been abandoned. Nevertheless, it might not be dominant in any given patient, and in each case it was advisable to ascertain to what extent the microbic infection as a whole contributed to the condition in relation to other factors rather than to perform many different bacteriological tests. A classification according to the importance of the infective factor would be headed by such diseases as gonococcal and meningococcal arthritis, followed by syphilitic diseases of joints, tendon-sheaths and bursæ; dysenteric fibrositis; and, finally, the arthropathies: Charcot's joints and syringomyelic joints; pure traumata leading to small hæmorrhages, and ruptures of synovial fringes leading to synovitis and arthritis.

The difficulty lay in the intermediate group, which included the factor of gout. The gouty patient demonstrated a tendency to metabolic—or purin—dysfunction which was in many instances activated by microbic subinfection. The treatment of this often produced relief, but a gouty patient always had a peculiar clinical picture different from that of other expressions of focal sepsis, and the removal of the infection would not dispose of the metabolic dysfunction. In the rheumatoid state there was usually an infective factor, but it was only one of many; others were lowered nerve tone, which lowered resistance to subinfection, and the nutritional factor.

Since dental sepsis was often closely related to fibrositis, a careful clinical and radiological search should be made for devitalised teeth, gum recession, deep pockets; "throwing-out" of the alveolar margin, indicating a local chronic fibrositic process; and "pyorrhœa sicca," a chronic dry fibrositic process probably induced by apical infection. Dead teeth, obviously infected teeth, and those with apical abscesses were sacrificed in chronic or recurring fibrositis, but where the periodontal membrane was thickened and inflamed with a certain amount of recession of the gum but the teeth were alive and mechanically useful, the patient should be expected to share some of the responsibility of removing them and should be told frankly that the result was doubtful. The septic tonsil was not so likely to be the big hyperplastic one as the small, blue, hard tonsil which, like the gum, gave an impression of being fibrositic—the impression that it had been subjected to a chronic, non-suppurative (the speaker stressed this qualification) inflammatory process. Sepsis was by no means synonymous with suppuration. The sinuses should be examined in the routine manner. The prostate should be suspected if there were any history, not necessarily of gonorrhœa, but one substantiated by prostatic threads or mucus in sedimented urine, whether organisms were present or not. Massage often gave good results. The urine in fibrositic patients rarely showed organisms if collected under sterile conditions. Sir Thomas did not advise speculative removal of the appendix or gall-bladder, but if there were clinical reasons, especially supported by radiological reasons, he gave the benefit of the doubt a little more readily to the fibrositic patient than he would to another.

Fibrositis might in some cases be due to a subinfection of tracts of mucosa rather than of its "belly-outs" or culs-de-sac. It might be profitable to examine the nasopharynx "by the square inch" rather than merely its "dug-outs." Intelligent appreciation of the importance of subinfection of the intestines had been hampered by the introduction of the horrible term "alimentary toxæmia." This might mean any one of a number of conditions, from the absorption of ptomaines or putrefaction products to protein sensitiveness. Microbic infection of the intestinal mucosa was, of course, not a toxæmia in the sense of intoxication; the French recognised the distinction very clearly.

In treatment, apart from acute microbic infections, there was very little indication for the use of bactericidal serum. Vaccines might, however—if the major premise were allowed that the condition was chiefly due to infection—be of value. The pyogenic cocci lent themselves readily to the production of antigens. According to Dr. Warren Crowe, the practitioner was inclined to abandon the treatment too early and to lose heart because the patient became sensitive; this was, according to Dr. Crowe, rather a cause for encouragement. Sir Thomas thought that vaccines were not given as good a trial as they should be in chronic intractible fibrositis. A boom in physical methods of treatment was overdue. It should not be necessary to send patients to the osteopath. Hundreds of milder cases were cured outside the control of the professions because practitioners did not take enough pains, and had not quite the right liaison with trained assistants. For muscles, massage was the most important form of treatment; for joints, passive leading to active movements under the direct supervision of the practitioner. In neuritis or sciatica the physiotherapeutic part of the treatment was the most important. Speaking of drugs, Sir Thomas said that the present age was one in which specificity in treatment and the linking-up of treatment with diagnosis were not popular. Personally, he preferred not to give drugs whose action he did not understand.

DISCUSSION.

Dr. C. E. SUNDELL said that, in the vast majority of cases, the bacterial factor was of no importance.

Why should fibrous tissue suffer from "-itis" and not other tissue? The striking difference was its relative avascularity, and the condition might be based in some circulatory anomaly. The first stage was capillary stasis of the affected parts, and it was then that treatment should be started, before the nodule developed. Heredity was extremely important; fibrositic patients manifested the adult stage of a life-history of which the juvenile stage was growing-pains. The temperature of the patient was always subnormal except under a stimulant—an indication of sluggish metabolism. Anomalies of skin secretion were very frequent; the skin was dry, and profuse sweating could be induced by certain stimuli, resulting sometimes in cure. Subject to the removal of septic foci, treatment was in the hands of the physiotherapeutist, who could stimulate the circulation and the action of the skin. Endocrine trouble might be a factor, and small doses of thyroid were often effective.

Dr. K. E. ECKENSTEIN said that in fibrositis the practitioner was dealing with a patient complaining of vague pains which were nevertheless very definite and difficult to cure. The only thing that he could do was to treat the patient to the best of his ability and hope for a good result.

Mr. P. JENNER VERRALL said that certain types of fibrositis—particularly tennis-elbow and painful heel—were almost always due to focal sepsis, usually an apical abscess. The question was not as vague as some speakers had suggested. The condition was governed by the good old orthopædic principle of circulating toxins, chemical or microbic, and a local trauma, which need not necessarily be an injury but was often a slight chronic irritation. The cure of tennis-elbow by the incision of Osgood's bursa was due to the opening-up of the deeper lymphatics. Patients with lumbago were often lordotic; their posture put a chronic strain on the erector spinæ which fatigued it so that all the strain was thrown on to the fibrous tissue. This was an example of chronic continued trauma, and any kind of circulating toxin was liable to affect that strictly non-vascular tissue, the attacks depending on whether the toxins were in the ascendant or not.

In physiotherapy, the acute case required not osteopathy but sedative massage. In chronic fibrositis a time came when the condition became an infiltration of the fibrous tissue of the fasciæ and possibly of the muscles; manipulation, preferably under an anæsthetic, was then the treatment of election.

Dr. TEMPLE GREY suggested that all children had growing-pains. The soil must be more important than the infection, or people in the lower classes, who often suffered from extreme forms of local sepsis, would suffer more from fibrositis. It might be useful to revise the old doctrine of individual temperament.

Dr. E. P. FURBER suspected that many of the modern remedies acted chiefly by psychotherapeutic means.

The CHAIRMAN said he feared the profession had all gone septic mad. Pyorrhœa was a disease of the gums, not of the teeth, and extraction should not be necessary in its treatment; he advocated salt solution. He remarked on the frequency of fibrositis in the medical profession, especially in surgeons, and inquired whether long hours in the humid atmosphere of the theatre were not to blame. He sought an explanation in the term "tissue indigestion"—congestion of the blood-vessels and lymphatics. This would account for the universality of the disease and its appearance even in animals and birds. He had immensely improved his own condition, of which the basis was undoubtedly hereditary, by rational dieting.

Sir THOMAS HORDER, in reply, said that capillary stasis was possibly one of the expressions of the inflammatory state, and that subnormal temperature and lowered basal metabolic rate showed a chronic infection to which there was a low grade of resistance. There was a trend of opinion in favour of raising resistance rather than combating infection directly. He had, he said, obtained good results from atophan provided that it was carefully given, three days at a time, with rest periods of three days, in conjunction with alkali treatment. He had never met a disaster from its proper use. It was a powerful detoxicator of purin derivatives in the liver.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

AT a meeting of this Section on Nov. 28th Dr. J. LAIT, the President, took the chair, and a paper on the prevalence of

Diphtheria Carriers among Dublin School-children

was read by Dr. R. A. Q. O'MEARA. He had, he said, taken nose and throat swabs from 1000 school-children between the ages of 3 and 13, and found morphological diphtheria bacilli in 50 (5 per cent.). In 41 (82 per cent.) of the carriers the organisms were isolated and subjected to fermentation and virulence tests. It was found that 2·3 per cent. of the 1000 children were carriers of virulent diphtheria bacilli, and he estimated that there were some 3000 carriers of diphtheria bacilli in the Dublin schools, of whom 1400 carried virulent organisms. The carrier-rate was higher for girls than for boys. The importance of nasal swabs in searching for carriers was shown by the fact that 25 of the positives were nasal carriers only; 18 were throat carriers only, while 7 were carriers in both nose and throat. The organisms were virulent in 44 per cent. of the nasal carriers, in 43 per cent. of the throat carriers, and in 68 per cent. of the nose and throat carriers.

The PRESIDENT asked what the clinician should do when he encountered these children, and how they were to be distinguished from early cases of diphtheria.

Dr. W. R. O'FARRELL referred to the intermittency of the carrier state, and its bearing on the results obtained in any locality.

Dr. M. J. RUSSELL, speaking as medical officer of health for Dublin, said that Dr. O'Meara's results showed a serious state of affairs, especially as the schools of the city were overcrowded. A clinic had been established for prophylactic inoculation of children before school age with toxoid-antitoxin mixture, and it was hoped that the incidence and mortality of the disease, which had shown a distinct upward tendency in recent years, would be lessened. He appealed to clinicians to assist in reducing the figures by prompt isolation of cases and by deferring the discharge of convalescents until they were shown to be free from diphtheria bacilli.

Dr. A. R. PARSONS asked what was the significant difference between virulent and non-virulent diphtheria bacilli, if the presence of the non-virulent bacillus was of any consequence, and if the non-virulent could change into the virulent type.

Dr. W. F. HOOPER suggested that the inculcation of cleanly habits into the poorer children in Dublin schools would help in reducing the number of carriers.

Dr. O'MEARA, in reply, said that the Schick test was a method—not however to be recommended—of distinguishing the carrier from the early case. The distinction could best be made on clinical grounds, and in cases of doubt serum should be given. The difference between virulent and non-virulent diphtheria bacilli was that the former were toxin-producing, whereas the latter were not. The non-virulent type was harmless and did not give rise to the virulent type. There was no necessity for giving antitoxin when only non-virulent organisms were present.

The PRESIDENT read notes on a case of cerebro-spinal fever.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

A MEETING of the President and General Council of King Edward's Hospital Fund for London, for the purpose of awarding grants to hospitals and convalescent homes, for the present year, was held at the House of Lords on Dec. 12th.

The Prince of Wales, who was in the chair, read the following message from the King:—

"Buckingham Palace.

"The King has learned with much satisfaction that the income of the Fund has enabled the distribution to be increased from £250,000 to £266,000, and that £116,000 has also been received on capital account. These gratifying facts themselves testify to the confidence which the Fund has established in the minds of the public, and must be a great encouragement to all its workers and well-wishers.

"His Majesty deeply regrets the death of Sir Otto Beit, to whose munificence the King's Fund is indebted for so large a proportion of the radium which it holds for the use of hospitals in London."

Increase in the Distribution.

Continuing, His Royal Highness said it was very fortunate that it was possible to increase the distribution this year from £250,000 to £266,000. It had remained at the quarter million for two years, and a good step forward had been made towards the £300,000 mark. This increase was made possible by three satisfactory features in the receipts. First, a donation of £10,000 from the anonymous friend who had during the past few years given seven sums, amounting in all to £54,000; secondly, there had been considerable additions to the capital fund, notably £90,000 under the will of the late Lord Revelstoke, for many years the treasurer, and the income from this capital was the solid foundation on which the annual distribution was based; thirdly, the legacies not earmarked for capital had now, for the third year in succession, amounted to more than £60,000, and the whole £60,000 had been received before November, when the estimates were made up. The combined result was that the distribution had been increased by £16,000, and the Fund was able to pay the special grants towards the pensions scheme for nurses and hospital officers, which come to about £16,000, without running any undue risk of not maintaining this progress in the future. The total amount distributed was thus £282,468.

PROGRESS OF THE VOLUNTARY HOSPITALS.

Voluntary hospital managers, like most other people the world over, were finding 1930 a difficult year. But, said his Highness, before we begin to talk about remedies, let us try to get the diagnosis right. There had been no evidence whatever of any gradual drying up of voluntary contributions during recent years. From the figures in the King's Fund Statistical Review down to the end of 1929 it would be seen that the number of beds was larger every year; expenditure, therefore, increased every year, but income more than kept pace; the aggregate surplus on the year's working increased from £17,000 in 1928 to £50,000 in 1929; surpluses were £3000 more, deficits £30,000 less; the total from voluntary gifts for all purposes in 1929 was £2,800,000. This referred to the hospitals in London alone. The figures for hospitals outside London were better still. For years this had been the normal general position of the voluntary hospitals, maintained, like all good things, only by constant effort, but nevertheless successfully maintained. The difficulties at the present time were exceptional. Taking all the hospitals together, during recent years, there had been a steady increase in income year after year.

IMPORTANCE OF THE VOLUNTARY SYSTEM.

It was important that voluntary contributions should be maintained. Efficiency could be secured in many different ways; but there were certain special characteristics with which the voluntary system permeated the whole hospital service of this country; and these characteristics had their origin in the close touch between the workers in the hospital, voluntary and paid, and that particular form of sympathy and public spirit which found expression in voluntary giving.

GROWTH OF THE HOSPITAL SAVING ASSOCIATION.

Voluntary contributions by patients themselves had been growing at a great rate, and he particularly referred to the contributions organised by the Hospital Saving Association, under the chairmanship of Sir Alan Anderson, by means of weekly workshop collections. The membership of the H.S.A. had grown from 62,000 in 1924 to 800,000 in 1930, and the total receipts from £22,000 to £438,000, all collected in threepences. As patron of the association, and as president of the King's Fund, which helped to found it, this information was known to him, but the other night he had seen a hall packed with 2000 men and women, all obviously in a state of enthusiasm over their job of putting up over 3*d.* a week out of their wages, and giving up their spare time to get others to do the same, in order to be able to contribute their fair share of the cost of hospital treatment for themselves and their families, and to help their mates to pay theirs, and thus to help the hospitals to treat those who could not afford to pay. If those wage-earners could thus continue, in ever-increasing numbers, voluntarily to contribute their share, in spite of the bad times, surely it was up to all the other members of the community also to contribute their share, and so make sure of keeping the voluntary spirit of mutual helpfulness as a permanent feature of our hospital service, under the new arrangements for coöperation between the county authorities and those responsible for the voluntary hospitals.

Distribution of Radium: Further Gift from Sir Otto Beit.

Besides the ordinary distribution they had to consider the allocation of the further 6 g. of radium which the Fund was able to buy because of the King's Fund share of the Thank-offering radium money, and the £10,000 from Mr. Roger Parr. This is in addition to the 4 g. bought in 1928 with the gift of the late Sir Otto Beit, whose death was such a grievous loss to all who knew him, and knew and valued the great work which he achieved by devoting so much of his

wealth, and also of his time and thought, to public objects, particularly the advancement of knowledge and the cure of disease. When the Distribution Committee prepared their report, there was a deficit on this additional 6 g. in the neighbourhood of £8000. This deficit no longer existed; for it was one of the last acts of Sir Otto Beit to authorise the honorary secretaries to say that he would himself make up whatever was required to pay for the balance. The King's Fund now held 10 g., and the method of concentrating the ownership of radium in the hands of a central body, which placed it out on loan, was well recognised to be one of the best ways of securing its most efficient use both for treatment and for the spread of knowledge. It was of the utmost importance that the new experience should be pooled, and should be acted on, as quickly as possible. Referring to the Thank-offering Fund, the Prince of Wales said it was interesting to know that the generosity of "Audax" in giving £105,000 to start that Fund was still bearing fruit. Recently an anonymous working man, in consequence of Mr. Audax's broadcasts, had made up his mind to send a guinea a year to the King's Fund for ten years. After sending 18 months' instalments, he had now sent the whole of the balance. Another interesting donation was the grant of £500 from the Naval Benevolent Trust, on behalf of the petty officers, non-commissioned officers, and men of His Majesty's Navy, in appreciation of the work done by the London hospitals for naval men and their dependants.

After referring to the interest of the Distribution Committee in the question of the time at which hospital patients are awakened in the morning, and to the increase in the grant to convalescent homes from £2000 to £3000, and to the Fund's indebtedness to Lord Luke and Lord Macmillan for services in connexion with the Road Traffic Act which ensured some payment to hospitals for the treatment of road accidents, his Royal Highness mentioned the loss to the Fund by the deaths of Sir Francis Champneys, Mr. Pett Ridge, Mr. T. P. Legg, and Mr. W. H. Marshall. He then welcomed back on the Propaganda Committee Mr. E. W. Morris, and concluded by moving a resolution of deep regret at the death of Sir Otto Beit, and the resolution, which contained a message of sympathy in her bereavement to Lady Beit, was passed in silence, the members of the Council rising in their places.

Treasurer's Statement.

Mr. E. R. Peacock (the treasurer) said that the anonymous donation of £10,000 was a most important addition to the income of 1930. The maintenance of the distribution had for many years depended on receiving one or more large donations, and every year one or two had been received, except in 1929, when there were, of course, large receipts through the Thank-offering Fund. The additions to the capital fund during 1930 amounted to £116,000. This included the legacy of £100,000 from the late Lord Revelstoke, which was reduced to £90,000 by taxation. This he regarded as one of the worst and least defensible forms of taxation. There were two other legacies of about £5000 each, one from the estate of the late Sir Frederick Eckstein and one from that of Mrs. Hames—an instalment of a much larger amount. There was also £15,000 from "Audax." It was indeed satisfactory that legacies available for general purposes should, for the third year in succession, have come to more than £60,000. Taking all these receipts into account, the Fund had been able not only to increase the ordinary distribution by £16,000, but also to meet the cost of the special grants in aid of expenditure on the Pensions Scheme, which came to just over £16,000, and to carry nearly £16,000 to reserve, where it would be available for use in case of future emergency. As the hospitals had for some time past added every year approximately 500 to the number of their beds, it was clear that to keep pace with the needs of the hospitals there must be a progressive and substantial increase in the amount of the annual distribution.

Lord Marshall, in making the annual statement on behalf of the League of Mercy, said that this year the League of Mercy proposed to allocate to the King's Fund the sum of £17,000 from its collections.

Grants to Hospitals and Convalescent Homes.

Sir Cooper Perry (the chairman of the Distribution Committee) presented the report of the Committee on the Distribution to Hospitals (including Recovery and Convalescent Branches), and moved the recommendation that the grants be approved.

The report stated that the amount placed at their disposal for allocation amongst hospitals and their recovery and convalescent branches was £263,000, as against £248,000 last year. The number of hospitals applying for grants was 141, as against 143 in 1929. The Ross Institute and Hospital for Tropical Diseases had withdrawn its application, and the Middlesex Hospital now applied in respect of the main hospital and the cancer wing as a single institution. As the General Council had increased the total to £263,000, the Committee had been provided with an additional £9000, corresponding to the amount added to the maintenance grants last year, and an additional £6000 to meet increased needs. The special grants towards expenditure on the Federated Superannuation Scheme for Nurses and Hospital Officers came to £16,468, as against £13,734 in 1929. By October, 1930, 97 hospitals had joined the scheme, as against 94 a year earlier; and more nurses and officers had joined.

The total of the present distribution, taking into account ordinary maintenance grants, grants towards capital expenditure, and special pensions grants, was £279,468, which did not include the allocation of approximately £60,000 worth of radium.

Sir Leonard Cohen (hon. secretary) having presented the list of awards the Rev. Owen S. Watkins seconded the motion, which was carried unanimously. Sir Cooper Perry then presented the report of the Committee on the Distribution to Convalescent Homes not attached to particular hospitals, and moved that the grants be approved.

This report stated that the president and General Council had this year fixed the sum available for distribution amongst convalescent homes not attached to any particular hospital in London at £3000, being an increase of £1000 over the amount of the annual distribution in recent years. The number of applications eligible for consideration amounted to 57, as compared with 53 last year.

Lord Luke (hon. secretary) presented the list of awards, and the motion, having been seconded by Sir James Kingston Fowler, was carried unanimously.

Second Allocation of Radium.

Sir Cooper Perry presented a report of the Committee on the second allocation of King's Fund radium to hospitals, and moved its approval. Lady Ampthill seconded, and the recommendation was carried.

The report summarising the present position showed that 10 g. of radium had been allocated among 24 hospitals. In a final paragraph the report stated that it was a source of keen satisfaction that through the generosity of Sir Otto Beit, Mr. Roger Parr, and other donors, the King's Fund should have been associated in the privilege of providing the voluntary hospitals of London with a therapeutic agency of great potency and one which still required wide experience and further research in the best methods of its application.

Arrangements for 1931.

His Royal Highness then detailed the arrangements for 1931, and expressed his regret at the retirement from the Council, owing to ill-health, of Mr. W. J. H. Whittall, who more than anyone else was responsible for the Superannuation Scheme for Nurses and Hospital Officers, a scheme which had now been adopted by more than 100 hospitals in London. If we took the whole country, the figures were 300 institutions; a result on which Sir Edward Penton, the chairman, must be congratulated, as well as Mr. Whittall. Sir James Kingston Fowler, who was unable to accept reappointment on the Hospital Economy Committee, would remain on the Council. His Royal Highness said he proposed to appoint two new members of the Council, Mr. Ernest Pooley and Wing-Commander Louis Greig; and to appoint Mr. Samuel, who was already on the Council and the Propaganda Committee, a member of the Revenue Committee. Major Ian Hay Beith was joining the Propaganda Committee in place of Mr. Pett Ridge.

The Lord Chancellor, the Speaker of the House of Commons, and the Governor of the Bank of England had again consented to act in his capacity as President when he went abroad in January next.

On the motion of the Earl of Donoughmore (chairman of the Management Committee), seconded by Dr. H. Morley Fletcher, resolutions were approved delegating powers to the various committees for 1931.

The proceedings closed with a vote of thanks to His Royal Highness, proposed by Major R. I. Tasker and seconded by Sir Walter Lawrence.

REVIEWS AND NOTICES OF BOOKS

Social Control of the Mentally Deficient.

By STANLEY POWELL DAVIES, Ph.D., State Charities Organisation, New York. With Foreword by FRANKWOOD E. WILLIAMS, M.D. London: Constable and Co. 1930. Pp. 389. 13*s*.

SINCE the publication of the Report of the Mental Deficiency Committee the social problem of feeble-mindedness has probably attracted more attention in this country than ever before. The issue of this book is therefore timely. The author has assembled with much literary skill a large accumulation of facts and figures relating to mental deficiency, and has woven them together into a most readable and instructive account of the evolutions which public opinion has undergone towards this subject in the last 50 years. With the beginning of the twentieth century, two events took place which lifted public opinion out of the apathy with which it had up till this time treated the question. These events were the development and application of the Binet-Simon method of testing intelligence, and the development of the eugenics movement, together with the discovery of the Mendelian laws of heredity. These events initiated what the author calls the period of "Eugenic Alarms." Pedigrees such as those of the Jukes, Kallikak and Nam families worked out by Goddard and Estabrook, and the studies of the Hill Folk, the "Pineys," the Dwellers in the Vale of Siddem by other writers all pointed to the conclusion that mental defect was inherited in substantial accordance with simple Mendelian formulæ. There followed the period of the social indictment of the mentally deficient. Practically all forms of antisocial behaviour came to be attributed to the causal factor of feeble-mindedness, and the logical conclusion emerged that the only effective way of dealing with the problem was to segregate persons thus afflicted for their whole lifetimes. Every feeble-minded person was regarded as a potential criminal. The author vividly describes how this policy of wholesale segregation was found to be unworkable and unnecessary. Financial considerations made it unworkable, while it was rendered unnecessary by the distinction which was seen to exist between the comparatively small group of defective delinquents, of whom the generalisation that they were all potentially criminal emphatically held, and the much larger group of defectives who, by proper training and care, could be educated to lead innocent and useful lives. These historical considerations are very clearly set forth in the first half of Dr. Davies's book. The last half is devoted to a description of the modern colony system for defectives, wherein the process of inculcating social habits and aptitudes is carried out, and whereby the subject is equipped to the best of his limited abilities to lead a happy and useful life in the general community.

The author has gone into his subject with a thoroughness that typifies the best American writings on social science, and he has produced a book which will be read with interest and profit by a much wider circle than that of the medical profession. Appearing at a time when the eugenic aspects of the mental deficiency problem are capable of being stressed at the expense of its administrative aspects, this book is especially opportune.

Hygiene.

A College Text-book for Non-Medical Students. By R. C. WHITMAN, A.B., M.D., Professor of Bacteriology and Lecturer in Hygiene, University of Colorado. London: Chapman and Hall, Ltd. 1930. Pp. 327. 12*s*. 6*d*.

Personal and Community Health.

Third edition. By CLAIR ELSMERE TURNER, M.A., Dr.P.H., Professor of Biology and Public Health in the Massachusetts Institute of Technology. London: Henry Kimpton. 1930. Pp. 443. 12*s*. 6*d*.

"HYGIENE" is intended for the use of non-medical students though medical students also will get much benefit from reading it. In the preface the author mentions that some of those who have read the manuscript have suggested that he uses too many technical and purely medical terms, but he rightly answers that those who intend to study hygiene must be prepared to extend their vocabulary before they can understand the new ideas which it is the object of their study to appreciate. Like many recent

American text-books this work exhibits a refreshing departure from the usual order of the subject matter. Realising that there must be some basis of scientific knowledge, however elementary, before it is possible to understand the meaning of hygiene and its purposes, the author devotes the earlier chapters to such problems as the physical and chemical basis of life and death and the nature of disease and heredity. For a book of this kind the presentation of the problems of inheritance and mendelism is exceptionally detailed. The author wisely omits details about the organisation and work of health departments with which so many semi-popular American books have dealt, and the topic of venereal diseases and sex hygiene are so fully covered by separate works that he has found it practicable to omit reference to them also. Otherwise the book is very complete and well arranged. Yet it must have the defects inherent to the dogmatic presentation of scientific questions, and here and there facts are mis-stated or placed out of their true perspective; but it should prove useful to lay persons studying for qualifications in hygiene, especially to school teachers, health visitors, and to those sanitary inspectors who have a sufficient foundation of general education to derive benefit from it. Indeed, members of the medical profession will find material in it which, while not readily accessible in medical literature, has a definite bearing upon the practice of preventive medicine.

Prof. Turner considers public health from the standpoint of what the college or professional man, who is not a sanitarian, needs to know in order to protect his family and meet his responsibility as a citizen. For this purpose his book supplies a substantial body of information presented in 18 chapters and two large appendices. In this edition much material has been omitted and new sections have been introduced. The book has many good features; it is well illustrated, the language is simple, and the bibliography is extensive. Most of the work, however, is of more direct interest to American than British readers and many statements made would hardly survive scientific investigation. We doubt whether it is wise to attempt to convey to non-medical readers so much information on a subject which depends for its understanding upon a sound knowledge of the natural sciences.

Nervous Indigestion.

By WALTER C. ALVAREZ, M.D., Associate Professor of Medicine, University of Minnesota. London: William Heinemann, Ltd. 1930. Pp. 279. 15*s*.

THE subject of this book must interest every general practitioner, for nervous indigestion is a complaint that he is constantly meeting, and it has certainly increased since the war. Dr. Alvarez has succeeded in writing an account of the subject that is both practical and stimulating. The difficulty of interesting and educating medical students in the care of "functional" cases is demonstrated by the general lack of understanding and appreciation often shown to such patients. Dr. Alvarez stresses the important fact that their symptoms are as real and as distressing as are those produced by many, if not all, organic diseases. Insight, tact, patience, sympathy are required in the treatment of nervous indigestion, and Dr. Alvarez in his final chapter quotes many well-chosen passages emphasising this point. The chapters on the taking of a history and on the handling of the nervous patient are admirable. The whole book is written in an amusing style; Dr. Alvarez is plainly sceptical of some current theories, and is no advocate of a "roughage" diet. The daily use of laxatives he strongly condemns, but his warm advocacy of the barbital group of drugs will not meet with general agreement. He makes no mention of valerian. The book deserves to be widely read especially by those whose experience is slight or is limited to hospital practice.

Études radiologiques sur le poumon et le médiastin.

By M. DE ABREU, de l'Institut Brésilien des Sciences et de l'Académie de Médecine de Rio. Paris: Masson et Cie. 1930. Pp. 200. Fr.50.

THIS book contains many original ideas. For example, the author stresses the importance of the tone of an X ray shadow from which, in his view, the depth of a lesion can be accurately judged. Taking the shadow of a rib as corresponding to one of 3 c.cm. of water, the corresponding figure for the heart would be 7·5 and the rib and heart superimposed would give tone of 10·5 to the shadow. On this basis the volume of a lesion is calculated as its square surface multiplied by the tone. In the first part of the book the author describes the principles of thoracic radiology and the various forms of pulmonary tuberculosis as seen by X rays, concluding with a summary and useful list of references. The second part is devoted to an account of the mediastinum and describes the normal and abnormal X ray shadows which occur and, of course, vary with the angle from which the radiogram is taken. The third part deals with the radiology of the heart and intrathoracic vascular system, and contains a list of references to work on the X ray examination of the mediastinum. The book contains 79 figures and 42 radiograms, which are very well reproduced, and it should be read by all interested in thoracic radiology.

Laboratory Pediatrics.

By JOHN D. LYTTLE, A.B., M.D., Assistant Clinical Professor of Diseases of Children, College of Physicians and Surgeons, Columbia University, N.Y.; Assistant Attending Physician, Babies' Hospital, Medical Center, New York. Vol. XX. Clinical Pediatrics Series. London: D. Appleton and Co. 1930. Pp. 189. With Vols. XIX. and XXI. 32*s*.

THIS book contains, in a summarised and tabulated form, the chief laboratory findings in children's diseases under the obvious headings.

The charts record the results in individual cases. The series of sugar-tolerance curves in different conditions is of especial interest, as is also the chart showing the seasonal variation of serum calcium. The author expressly disclaims any intention to produce a laboratory manual, and in order to cover the ground in a book of this size brevity has clearly had to be a leading consideration. Space might, however, have been saved in certain places in order to allow expansion elsewhere, for example, illustrations and descriptions of intestinal parasites could have been omitted, since they can readily be found in the appropriate literature.

The book as a whole makes available in a compact form a considerable body of sound information which has not been previously collected in one volume. The material is almost exclusively American, but the conclusions are of general application, and we notice no omissions of importance. It will be found a useful and reliable work of reference.

THE LANCET.

LONDON: SATURDAY, DECEMBER 27, 1930.

A PUBLIC HEALTH CODE.

THE chaotic state of our local government and public health law is a remarkable tribute on the one hand to our national good temper and on the other to the competence of our local government officials. But there is no virtue in mere chaos. Everyone, therefore, will welcome the announcement that the Ministry of Health, having tidied up the poor-law statutes in 1927 and again in 1930, is now going to attack the law of local government and public health. A committee of departmental and other experts, whose names we announced last week, has been appointed to consider the preliminaries of rewriting the existing legislation in orderly form, the heads under which the new law should be grouped, and the amendments deemed desirable for facilitating consolidation and for securing simplicity, uniformity, and conciseness.

The effort is overdue. Even apart from last year's changes, twentieth century local government could not go on indefinitely under nineteenth century statutes. To name but a few Acts which the committee will have to consider, there are the Municipal Corporations Act, of 1882, the charter of the boroughs, the Local Government Act of 1888, which created county councils, and the Act of 1894, which created parish councils. Somewhere in the statute-book, but in no easy place to find, search will reveal the attributes of that elusive but important entity, the county borough, sometimes wearing the clothes of a county council, at other times those of a municipal corporation. Then there are the landmarks of the movement towards fewer and larger local authorities, the Rating and Valuation Act of 1925, and the Local Government Act of last year. The latter, while inventing guardians' committees and public assistance committees, abolished the guardians themselves but preserved, somewhat obscurely, a bundle of clauses as to guardians' qualifications, elections, and term of office, because these otherwise repealed enactments were (by a wicked but convenient stroke of legislation by reference) needed for rural district councillors. Almost every local authority has its statutory peculiarities in matters which often could be standardised and governed by one common code. For instance, the disqualifications for membership have petty variations for which there seems no better justification than the muddle of piecemeal legislation. Diversities in matters like audit may be inevitable but close examination may discover opportunities for simplification. As for the Public Health Acts, they contain masses of irrelevant police provisions. The main public health law is based on an Act of 1875. A text-book writer would have to take account of amendments and extensions under 40 or 50 subsequent statutes. Here, too, there is the added complication of the difference between the general and the local law. Once again the report of the Select Committee on Local Legislation is recommending that a new Public Health Bill be "introduced without delay" in order to save time and money by making universal the powers given by local Acts to individual councils in the past five sessions. The question of raising the general standard of public health by progressive legislation must, however, be kept separate from the question of consolidating the existing enactments. The Health Ministry's new committee is concerned with the mechanics rather than the merits of the law. It would be unfortunate if reformers blocked the sensible and clear re-statement of existing legislation in their desire for substantial advances. That would be a misunderstanding of the limitations of the committee's task. Indeed, as was the case in recent poor-law legislation, it is necessary first to find out and declare the existing law, before fresh reforms can be framed. The new committee will busy itself with no other amendments than those which serve to clear the ground.

When will the committee's labours show tangible results? Some think in three years, others in five. We trust that Lord CHELMSFORD will prove a chairman who can drive a willing team fast enough to falsify these estimates. A period of minority government in Parliament, when the Cabinet cannot make progress with substantial party measures, is the very time for passing Bills of the kind which the new committee will evolve. The committee, we understand, has already met. Its personnel is well chosen. Outside interests are represented while, on the departmental side, there are experienced legal advisers from the Health Ministry and the Home Office and (for this is largely an expert draftsman's task) a strong contingent of present and former Parliamentary Counsel. Probably the work, when complete, will leave ragged edges on other sides of public administration—education, for instance, the law of highways and those subjects with which the Home Office is concerned. Their turn for clarification will come. Meanwhile, is it too much to ask that the proposals for the new local government and public health codes should be available in print next year?

AGRANULOCYTOSIS.

WHEN SCHULTZ,[1] in 1922, described agranulocytosis he believed it to be an entity, probably caused by a specific micro-organism or some other toxic agent. Clinically, the condition he described is characterised by necrotic ulceration of mucous surfaces, usually about the mouth, with pyrexia and extreme prostation. The blood picture is peculiar, including leucopenia with complete or almost complete absence of granular polymorpho-

[1] Schultz, W.: Commun. to Verein für Innere Med. und Kinderhk., July 3rd, 1922.

nuclear cells—neutrophils, eosinophils, and basophils alike. The red cells and platelets, he said, show little or no diminution and there is no departure from normal in bleeding or coagulation times.

Since these observations were published many similar cases have been placed upon record, but no agreement has been reached about ætiology. The search for a causative organism has been fruitless, and the claims of various bacteria isolated from surface lesions and from the blood have none of them been confirmed. In opposition to SCHULTZ various workers have pointed out a close relationship between the blood picture of agranulocytosis and that of other conditions whose ætiology is to some extent understood—notably, certain toxic states. The most important poisons so far implicated belong to the arsenobenzol group of drugs; it remains uncertain whether it is the arsenic or the benzol which is the toxic agent, but in view of the well-known action of pure benzol upon bone-marrow it seems reasonable to blame the latter. Numerous cases of agranulocytosis following arsenobenzol therapy have been placed upon record, and AUBERTIN and LÉVY,[2] while inclined to suspect the benzol radicle, point out that cases have also been recorded after the use of bismuth preparations and in at least one instance of untreated syphilis. They think that syphilis may act as a predisposing cause by damaging the bone-marrow and thus rendering it susceptible to toxic agents, such as bismuth, arsenic, and benzol. SCHULTZ, while freely admitting that the blood picture may be brought about by various poisons, regards all such cases as secondary or associated, to be strictly differentiated from pure agranulocytosis. At the same time, it is almost impossible to dissociate his pure agranulocytosis from numerous other well-recognised conditions. Thus, with the addition of hæmorrhagic manifestations and a diminution of the platelets, the picture, both hæmatological and clinical, becomes that of the "aleukia" of FRANK, and this again may be indistinguishable from acute aplastic anæmia; while without an examination of the bone-marrow both these conditions may be indistinguishable from "aleukæmic leukæmia." Finally, an almost identical picture may appear in the course of chronic trinitrotoluene poisoning. BENHAMOU [3] is strongly of the opinion that agranulocytosis constitutes a syndrome whose actual appearance may be brought about by the action of divers toxic agents, but only if there is an innate susceptibility of the blood-forming system—in other words, a diathesis. Critics may say that the appearance of a "diathesis" in a French survey of such a subject is inevitable, but there is much to be said in favour of BENHAMOU'S view. All hæmatologists from time to time come across bloods with a marked diminution of the polymorphs, usually showing moderate leucopenia with a lymphocyte percentage of anything up to 50. The subjects, as a rule, are females, and may be in perfect health, though they generally have a tendency to contract minor infections. Such people may reasonably be regarded as possessing an agranulocytic diathesis. BENHAMOU points out that even in "pure" agranulocytosis the leucopenia described by SCHULTZ is not necessarily present. Cases have been reported with a white cell count of 10,000 and more, though the cells have always been all, or nearly all, mononuclear. BENHAMOU himself has shown that even in cases with a leucopenia it is possible by the injection of adrenalin—a procedure first recommended by A. G. GIBSON [4]—to raise the white cell count to 10,000 or more, but even so the added cells are all mononuclear.

The differential diagnosis of agranulocytosis has many pitfalls and the condition is probably far commoner than the diagnosed cases indicate. The necrotic and ulcerative lesions about the mouth may lead to a diagnosis of diphtheria, of Vincent's angina, or even of aleukæmic leukæmia. From the first two of these conditions it may readily be distinguished by examination of the blood, but it may be impossible to establish the diagnosis from aleukæmic leukæmia without examining the bone-marrow. The severe toxæmia and pyrexia may lead to a suspicion of typhoid, pneumonia, or some other acute infection, and here the response to adrenalin may give valuable aid. The appearance of bullæ and vesicles either upon mucous surfaces or skin may simulate pemphigus, chicken-pox, or even small-pox, but the leucocytic formula of blood or vesicular fluid should serve to differentiate it from these. Were the blood examined with more frequency in grave ulcerative conditions associated with fever the condition would probably be diagnosed far more often.

A striking peculiarity of the "pure" agranulocytosis is its predilection for the female sex; over 80 per cent. of recorded cases of this type have been in females. This peculiarity does not, however, extend to cases occurring after arsenobenzol treatment—possibly because of the greater employment of such treatment among males. Among the cases following antisyphilitic treatment a few recoveries have been recorded; apart from these the issue has been almost always fatal. A few cases have been reported in which the patient has recovered sufficiently to be discharged as cured, but in several of them there has been recurrence and death within a few months. These cases offer some evidence in favour of belief in the importance of the constitutional factor. Such recorded cases as have survived have been treated by leucocytogenic agents such as turpentine or milk injected intramuscularly. Where a fixation abscess results, recovery—temporary at any rate—may be looked for; but it remains doubtful whether the fixation abscess is really useful except perhaps for prognosis. In most conditions where the system retains enough reactive power to produce a fixation abscess recovery will be the rule. BENHAMOU advocates the injection of adrenalin along with the leucocytogenic agent, and at least it can do no harm.

THE FUTURE OF SURGERY.

THIS is an age of prophecy; during the last few years a series of essays on the future of almost everything has appeared in print, and recently more than one eminent surgeon has discussed the future of his art. The latest addition to the goodly fellowship of the prophets is Dr. A. F. HURST, who, in *Guy's Hospital Gazette* for Dec. 13th, considers the future of surgery. This he places in the hands of the general practitioner. More accurate diagnosis, he thinks, will rob the surgeon of a very high proportion of his patients. Dr. HURST, in illustrating his thesis, naturally thinks of disorders of the gastro-intestinal tract. He recalls an occasion 23 years ago when it seemed inconceivable that duodenal ulcer, which at that time had never been diagnosed at Guy's Hospital, could be a real and common condition masquerading as the familiar acid dyspepsia of the medical out-patient department. The treatment underwent a violent revulsion from mist. gent. et sodæ to radical operation, but Dr. HURST still believes—and is certain that surgeons agree with him—that the best treatment lies in some middle way. The possibilities are suggested by the history of gastric ulcer during the last 25 years. The student of to-day, in his opinion, will be able by the time he goes into practice to recognise the earliest symptoms suggesting the presence of an ulcer and to confirm his suspicions with the aid of the radiologist—and possibly also of the biochemist if a test-meal and the search for occult blood in the stools is beyond his own powers. If an ulcer is present he will give the only adequate treatment: rest in bed on a strict diet for four, five, or more weeks until all pain, tenderness, and rigidity have gone, the last trace of occult blood has disappeared from the stools, and there is no longer radiographic evidence of an active ulcer. He will then treat thoroughly all foci of infection in the mouth, throat, and nose, and will instruct the patient in the régime which he must follow for the rest of his life if he is to remain free from symptoms.

Even cancer and gall-stones, Dr. HURST thinks, will trouble the surgeon of the future in very small numbers only. Just as there are bound to be a few cases of perforation of an ulcer in patients who have had such slight symptoms that they have not sought advice, so there will be cases of malignant disease which must be removed. Dr. HURST, however, confidently hopes that the prevention of cancer will be in sight 25 years from now. Here again much depends on the general practitioner, who has first of all to learn that indigestion of any kind or loss of appetite, occurring for the first time in a patient over 40 years of age and not responding to simple treatment within a week, demands further investigation. Cancer, in Dr. HURST'S opinion, never develops in a healthy stomach and the care of the practitioner in preventing and treating ulcer should prevent one-fifth of all cases of carcinoma of the stomach. The remaining four-fifths have achlorhydria or very low acidity, probably due to an antecedent chronic gastritis, which again it is the duty of the practitioner to find and treat. Unfortunately only a few cases of chronic gastritis show direct symptoms, but they usually result from some easily recognised cause such as acute food poisoning and gastric influenza. Even if the patient appears to have recovered completely from these conditions, a test-meal should be given a month or two afterwards and any achlorhydric gastritis revealed should be treated without delay. Most other cases of chronic gastritis, he says, are the result of excessive cigarette-smoking, alcoholic excess—especially on an empty stomach—pyorrhœa, or chronic infections of the tonsils or nasal sinuses. "Medical" cholecystitis is commcn enough but too rarely diagnosed. Most of the cases are cured by hexamine in doses up to grs. 300 a day given with sufficient alkalis to keep the urine completely alkaline, especially if combined with "drainage" of the gall-bladder by magnesium sulphate given before breakfast. If early cholecystitis be treated in this way the future of gall-bladder surgery should be a blank page.

The only scope which Dr. HURST gives to the surgeon of the future is in tumours of the brain and chest, but he ventures to hope that the work of CUSHING, TUDOR EDWARDS, and MORRISTON DAVIES may lead to earlier diagnosis and an advance comparable to that in abdominal surgery.

MINERVA.

THE thirtieth edition[1] of the Year-book of the Learned World with the well-known title has reached the limit of size. The present edition is 25 sheets larger than the last, although many of the entries have been shortened, and at its present rate of growth the next edition would be at least 20 sheets larger. Dr. Gerhard Lüdtke, who has edited the Year-book since 1905, considers that the limit of price has also been reached, and he hopes to find some different arrangement of the material by which to effect some economy both in cost and size. As a work of reference Minerva is amazing in its inclusiveness and accuracy. Its editor tells of difficulties in getting full details from Japan, with which he is now satisfied, and from Russia, which still leave something to be desired. But even the trained expert seeking to verify something outside his usual works of reference will rarely be disappointed in his search, although in this issue the names of assistant professors in American universities and colleges have been perforce omitted, those of associate professors being retained. It seems to us doubtful if compression or abbreviation could usefully be carried further without making reference less easy, for the list of contractions and symbols already occupies nine columns of the preface, and the office of Regierungsobermedizinalrat is represented by ROMR. The publisher suggests that Minerva would be found useful abroad in all scientific institutions and libraries, as well as to editors and publishers in general. It is our experience that anyone who uses it becomes an addict.

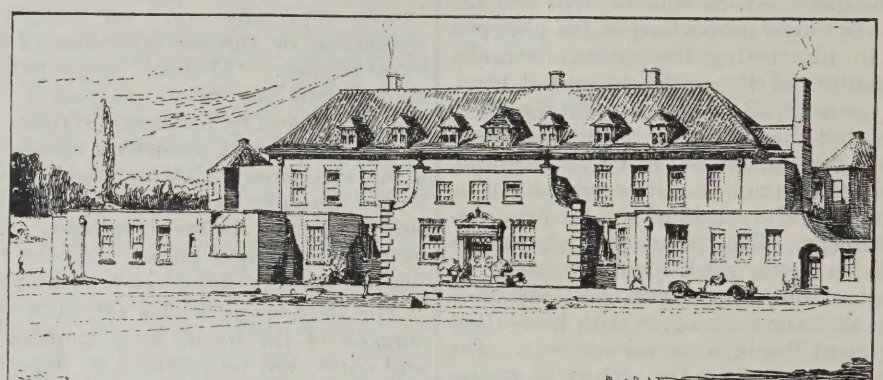
ANNOTATIONS

THE SCHOOL SANATORIUM.

THE rising walls of the new sanatorium of Epsom College remind us of the part which the sanatorium plays to-day in the administration of a big public school. Sixty years ago few public schools made large and organised provision for dealing with epidemic disease among their charges. There would be accommodation for accidents, and where the separate house system existed the housemaster, and whoever might act as his matron, were prepared to deal with the sick boys in their particular establishments. When the value and even the necessity of a sanatorium or infirmary was perceived all this was changed speedily, and every large public school possesses to-day accommodation for the sick of the school and its environment, the medical officer of the school acting ex officio as the medical director. So far the pattern is common but variations exist alike in the accommodation which is offered at one school and another and in the quality of the service, nor is there any hard-and-fast rule for the number of beds that should be held in readiness in relation to the numbers in the schools. What this percentage should be is not easy to decide; the ratio of 15 per cent. is usually accepted as the right one, but a case could be made out for a larger or for a smaller ratio. A large number of factors must be reviewed. The public schoolboy nowadays has often led such a protected life at home and at a preparatory school that his five years at a public school may be the period in which he will be attacked by what used to be regarded as the inevitable exanthemata. In such a susceptible community one case introduced from without may produce many cases within; in other words, the number of beds available must have some relation to sudden emergency. Whatever the number of such beds may be in proportion to the number of boys in the school, there must also be beds somewhere for the case that requires watching. These patients if isolated early may be found to be sources of danger, and their prompt segregation will prevent any large call being made upon the general accommodation of the sanatorium. The watching can be to some extent carried on in the boarding houses, but that implies spare rooms of adequate character in those houses. The two different methods of attempting early interference in the possible presence of an epidemic accounts for some of the discrepancies which we may find in the size of the various sanatoriums in relation to the numbers totalled by the schoolboys and those in immediate relation to them—the latter being often within a third in size of the numbers in the school.



Epsom College Sanatorium from the north-west.

Yet another reason exists for a generous supply of beds. The medical officer must have an opportunity of isolating the contacts, and that accommodation should be available during the holidays as well as during the term time, for sickness may break out inconveniently near the end of the term, when the public danger is now perceived of distributing a large number of lads to different parts of the country with the seeds of infectious disease already sown. With, no doubt, certain of these reflections in mind the sanatorium in building at Epsom is large in proportion to the size of the school. But here two other arguments obviously exist for the erection of a large institution. First, the school is rapidly growing in response to its recognised position as one of the great public schools of the country; while, secondly, through its foundation it has so close a connexion with the medical profession that a falling off from a high medical standard would be discreditable.

FINALITY IN CRIMINAL TRIALS.

IN 1927 a man was tried at Edinburgh on the charge of having murdered his mother, and the jury, by a majority verdict, found the charge "not proven." This result was correctly stated in our recent review of the volume containing the account of the case in the Notable British Trials series. The reviewer, in venturing the comment that it was perhaps a little hard on the accused that so recent a case should be so soon re-tried on paper, spoke of him as a man "recently *acquitted* of murder"—a description technically incorrect when applied to a case resulting in a verdict of "not proven." A friendly critic, who will sympathise with the Englishman's difficulty in appreciating the niceties of Scottish procedure, points out that the verdict of "not proven" is strictly not an acquittal; it permits of a re-trial, should new evidence at any time arise. If there were any question of a re-trial on the murder charge, the reviewer's criticism (that the editorial introduction to the report of the trial conveys a strong opinion upon the causes of the death) would, according to English notions, be equally valid. Meanwhile, the distinction between the English and Scottish forms of criminal procedure is worth noting. In England (in the absence of any element of insanity) the verdict is either "guilty" or "not guilty"—in other words, either a conviction or an acquittal. And, as it is an established principle of English law that a man may not be put twice in peril for the same offence, he can successfully plead (in the old law-French phrase) "autrefois convict"

or "autrefois acquit," if he is tried again upon that identical charge. The only form of re-trial in such circumstances in England is where the jury has disagreed. It is surprising how seldom this happens when the requirement of unanimity is borne in mind. A disagreement means no verdict at all; the case then comes on again, usually at the next assizes. On the whole it is unlikely that an English jury will find a man "guilty" after the previous disagreement of another jury. Indeed, if two juries disagree and the case comes before a third jury, it is usual for the prosecution to offer no evidence—which means that the accused gets his acquittal at last. It may also be noted that the Court of Criminal Appeal has no power to order a re-trial in England. The functions of the court in ordinary cases are three: (1) on an appeal against conviction, it can allow the appeal, if it thinks that the jury's verdict is unreasonable or not supported by the evidence, or that the judgment was brought about by a wrong decision of a point of law, or that there was a miscarriage of justice—in any other case it must dismiss the appeal; (2) if it allows an appeal against conviction, it must quash the conviction and direct a verdict of acquittal to be entered; (3) on an appeal against sentence it can substitute a sentence either more or less severe. Many critics think that, where an appeal against conviction has succeeded on some technical ground, the court should have power to order a re-trial; but Parliament does not allow this course. When the Criminal Appeal (Scotland) Act of 1926 set up a similar system of criminal appeal in Scotland, the power to order a re-trial was still withheld. But the Scottish Court, dealing with criminal appeals, has here one power which the English Court does not possess. On an appeal against conviction the court in Scotland is empowered not only to quash the conviction but also to quash the sentence passed and to pass another sentence as if the appeal had been an appeal against sentence and not against conviction. Such are some of the minor differences between English and Scottish criminal law, in addition to the much wider distinctions arising from variations in the legal system, the arrangement of courts, and the statutes applicable to the two countries. In England, of course, there would have been a prompt investigation by the coroner; sworn evidence would thus have been available at a very early stage.

THE NERVOUS TEMPERAMENT.

No part of medical practice more persistently eludes any scientific classification than that dealing with the temperamental variations of individuals and their different reactions to stress and strain. A host of vague generalisations, hazy conceptions, and unadmitted ignorance has been concealed under the term "nervous" and its many alternatives. Dr. Millais Culpin and Miss May Smith, D.Sc., working for the Industrial Health Research Board, have attempted to break the ground around this difficult problem and, although they say that their work is no more than disturbing the surface of this important field, yet their results are of the greatest interest.[1] Over 1000 people of both sexes have been interviewed while actually at work, and the authors think that it is possible as the result of a single interview to elicit nervous symptoms or tendencies and classify individuals according to the amount and severity of the symptoms. When the classification had been made, it was found to agree with independent judgments as to efficiency and capacity for adaptation, and with the results of the dotting test. A curious feature of this test is that obsessional subjects are peculiarly good at it. When the nature of the obsessional temperament is considered, this is less surprising than it seems at first sight, but it should prove a useful aid to diagnosis. As has already been shown by other observers, nervous illnesses depend upon occupational conditions as well as upon predisposition, and a "bad" subject may carry on contented and excellent work under good conditions of employment but break down completely if circumstances become difficult.

The applications of this research to industry are obviously of the first importance. In the first place the heavy absenteeism in some firms from sickness labelled "nervous breakdown" or one of its equivalents could be almost entirely prevented by selection of candidates and sensible attention to conditions of employment. Secondly, there is the choice of supervisors who can undertake the responsibility of direction without undue strain and who are able to oversee the work of others without getting on the nerves of everybody under them. Thirdly, there is the problem, known to all industrial concerns, of the erratic worker who oscillates between very good and very bad work for no apparent cause. Last, but not least in importance, is the question of alleviating the disproportionate suffering of some individuals under conditions of noise, stuffiness, or other unpleasantness which do not worry their neighbours in the least. The findings of the investigators cannot conveniently be summarised, but "nervous" symptoms were found in a very high proportion of employees examined—sometimes as many as 50 per cent. Men and women in authority suffered less than lower grades, promotion apparently acting as a form of selection in this respect. The student group had a higher percentage than the factory group, and women dramatic art students showed a very high percentage of the obsessional type. Finally there was evidence of correlation between the results of the experiments and stigmata of discomfort, such as inability to bear noise and dissatisfaction with work and environment.

SUN-BATHING IN A LONDON PARK.

Dr. George Sowden, medical officer of health for St. Pancras, reporting upon a sun-bathing centre in Regent's Park which was opened in August, states that the building is of brick, one-storey high, and measures 30 feet in length by 20 feet in depth. It is divided by folding doors, and each half contains sanitary accommodation and a shower bath. The Sunlight League undertook to provide the salary of a competent supervisor from the date of opening until the end of September, and the centre was open daily from 10 A.M. to 1 P.M. and from 2 to 6 P.M. The children admitted were between the ages of 2 and 5 years. They were not suffering from any definite illness, but were selected from those attending the various welfare centres in the borough as being likely to derive benefit from this form of treatment. The parents were required to sign a form accepting all responsibility in connexion with the child's attendance and were asked to provide a towel, bathing slip, and a sun hat. The children were arranged in groups according to their susceptibility to sunlight; each child was weighed at the first attendance and subsequently once a week. During the brief heat wave in the last week of August and the first few days of

September, the attendance was very good, but it fell off during the remainder of the period when the weather was extremely unsatisfactory. The total number of children entered on the register during the seven weeks the centre was open was 148, and the number of attendances each week was as follows: 44, 90, 293, 249, 152, 112, 86, making a total of 1026. It is difficult, Dr. Sowden says, to express an opinion about the effect on the health of the children. In 33 who made 10 or more attendances, there was an increase of weight in 30, varying from ½ lb. to 2¼ lb. The greatest increase was recorded in the case of two children (brothers), who made the highest number of attendances—namely, 29—and whose weight increased by 2 lb. 2 oz. and 2 lb. 4 oz., respectively, a rate of increase much in excess of the normal. In a few cases, children of a nervous, excitable type, who usually slept badly, were stated to be less restless and to be sleeping better. Some improvement in appetite was also recorded. The general conclusion drawn from the experience gained is that it would be difficult and expensive to maintain a centre exclusively for sun-bathing. During bad weather, although the staff would be in attendance, the number of children would be small or even nil. Dr. Sowden is of the opinion that it would be preferable to combine a sun-bathing centre with a day nursery or nursery school.

EXPERT EVIDENCE ON GUNSHOT WOUNDS.

THE life of a person accused of murder often depends on the expert evidence of the toxicologist but equally often on expert evidence about firearms and gunshot wounds. Frequently a medical man is called upon to give this evidence, although a study of the subject forms no part of the training even of an expert pathologist. We publish on another page an account by Dr. W. Stewart of a case in which his careful experiments and evidence extricated an innocent man from a convincing net of circumstantial evidence. In the *Analyst* for December Mr. G. W. Baker describes an investigation he was called upon to make in Jaffa, and which brought a guilty man to justice. This case is of great interest, as it is the first occasion on which X rays have been used in the examination of bullets for forensic purposes. The nose of a bullet was found in one of the bodies of a murdered family, and its peculiar nose-filling of lead and fibre was readily detected by radiology without mutilating the exhibit. A comparison with 32 different makes of ammunition of the same calibre helped to establish the fact that it was from British ammunition as used by the police. Among the empty cartridge cases found about the room was one which lay in a pool of clotted blood in such a way as to show that the blood had flowed round it and that it had not been dropped some time after the crime. This case was brightly polished—a fact which first threw suspicion on the police. Cartridge cases from the accused's rifle had three characteristic features in common with each other and with this exhibit. The first was a bulge on the side of the case diametrically opposite the extractor mark. It was found, however, that the degree of bulge might vary with the same rifle, and that if it were present at all in a rifle it always bore the same relation to the extractor mark. The second feature was an extractor mark characterised by a series of deep cuts with rounded ends parallel with the rim, and at right angles to these a series of long scratches produced on extraction. There were considerable variations in the extractor marks on different cases fired from the suspected rifle, but in Mr. Baker's opinion there was sufficie evidence to identify the rifle. The third feature w a characteristic pattern of at least 14 marks at t bottom of the pin impression in the cap of the ca tridge case; the general shape of the impressio was found to be sufficient to identify each of t rifles tested. Moreover, the pin impression cou only be produced by the act of firing and not b practice loading and unloading. It was a delica matter to obtain photographs of these impressio They were taken through a one-inch objective a the stage of the microscope was removed so th the case could be held vertically and slowly rotat in a slanting beam of light. The equipment used these investigations included a comparator eyepie a camera lucida, and a micrometer eyepiece. obtain bullets from firing tests in a fit state for co parison, Mr. Baker used a special box divided in six equal compartments by removable cardboa partitions. The first two were filled with cotton was and the others with fine bran; at about four yard range the bullets came to rest in the fourth or fif compartments with little distortion.

As Mr. G. H. Perry, chemist at the War Depar ment, said in a discussion after Mr. Baker's pap it has become possible in the last few years to identi conclusively cartridge components with the weap used. Complicated and delicate instruments a required, and the greatest possible care should b taken of the exhibits to avoid any damage or di tortion. Modern work on firearms is as refined finger-print detection. It needs an expert for i execution, but all medical men ought to be acquaint with its possibilities, as it is the doctor to who appeal will first be made for expert evidence and w very often has the first opportunity of preservi important exhibits.

TREATMENT OF CUTANEOUS TUBERCULIDE

SUBCUTANEOUS and intramuscular injection cod-liver oil and its derivatives has been employe for more than a decade as an auxiliary treatme in tuberculous affections of the skin, bones, a connective tissues. In the condition known lupus pernio, for example, the subcutaneous injecti of 5–10 minims of sodium morrhuate has been fou satisfactory, and on occasion has even brought abo a cure. Jaczewski's use of iodo-morrhuate[1] an outcome of these tentative methods and has be modified by O. Blatt,[2] who recommends a solut of 1 part of tincture of iodine in 20 parts of cod-liv oil, 5 c.cm. being given by intramuscular injecti every 14 days. He does not give iodine by t mouth, as advocated by Jaczewski, and substitut topical applications of cod-liver oil for iodine paintin of the local lesions. The theoretical considerati which underlie the treatment are interesting b highly speculative. They concern the respecti rôles of the fat and lipase metabolism in infect persons, and their reactive potentialities in t biology of Koch's bacillus. Blatt lays stress on t almost specific action of cod-liver oil as compar with other oils (e.g., olive oil), and suggests th its advantage may be a function of the vitam content. For this reason the cod-liver oil injected not previously sterilised by heat, all danger of sep being precluded by the 5 per cent. iodine in the mixtu which is said also to elicit a more potent and pr tracted local reaction with the production of lymph

[1] Przegl. dermat., 1928, No. 3.
[2] Dermat. Woch., 1930, xc., 741.

cytosis. Five to ten intramuscular injections of 5 c.cm. at fortnightly intervals represent the average dosage for adults. In most of them—and with consistent regularity in lupus—fever began to develop on the sixth day. Its maximum was usually on the ninth, and thereafter the temperature fell to normal by lysis, rarely by crisis, in a few days. The reaction, Blatt says, appears to be an essential feature of the treatment and proceeds pari passu with local swelling, hyperæmia, and pain at the site of the injection. In not a few cases a focal reaction was noted in the lupus lesions, which for the time being were distinctly aggravated. The end-results were, however, definite and encouraging; "the patients' general condition was improved, tuberculous ulcers and sinuses after operations healed promptly, and recurrences were rarely observed." Blatt confirms the statement that "lupus vulgaris can be completely cured by this procedure alone." Though he does not give details or results in tabular form, he states that 120 cases of lupus vulgaris, two of tuberculous verrucosa cutis, six of disseminated papulonecrotic tuberculides, and five of erythema induratum of Bazin responded favourably. In five cases of lupus erythematosus in which the evidence suggested a tuberculous ætiology, the method completely failed to give relief. Blatt's conclusions are: (1) that Jaczewski's injections afford a rapid and certain cure of the ulcerative types of tuberculosis cutis; (2) that they may be regarded as the method of choice in the treatment of all types of tuberculide; and (3) that in the treatment of lupus vulgaris the method is a valuable auxiliary to local measures.

THE DENTISTS REGISTRATION FEE.

COMPLAINTS have been heard from dentists that they have to pay a substantial fee annually for their entitlement to practise, whereas a single fee ensures their medical colleagues a place on the Medical Register. A memorandum issued by the Registrar of the Dental Board and printed as an appendix to its minutes sets out the official reply to this and certain other prevalent misconceptions. The Dentists Act of 1921 laid down as a return for the right to practise dentistry given to registered persons that a fee should be charged each year for retention of the name on the Dentists Register. This fee is akin to the payment made annually by solicitors and auctioneers. The Act laid down that it was not to exceed £5; at the present time it is £4. Solicitors in London have to pay £9 and in the country £7 for their annual practising certificate. The fee might have been made payable to the State through the post office or some other agency, but it was made payable to the Board and the Act laid down that, after covering the expenses of the Board, the money should be allocated to purposes connected with dental education and research. Thus while the primary function of the Dental Board is to protect the public by keeping a Register on which is entered the names of all properly qualified persons who desire to practise dentistry, and by removing therefrom the names of persons in whose personal conduct the public can no longer have confidence, the secondary function of the Board is to collect the fee prescribed in exchange for the granting of the right to practise, and to expend moneys so received, and not reserved for their primary purpose, upon "dental education and research or any other public purposes connected with the profession of dentistry." The memorandum insists that the Board was established for the benefit of the public and not for the benefit of the dental profession. It is in no sense a professional protection society, and dentists who desire to combine to further their own interests must become members of some society of their own for that purpose, such as the British Dental Association, the Incorporated Dental Society, or the Public Dental Service Association. The Board is not concerned with the fees which dentists may charge or with the remuneration which they may receive. The only benefit which dentists are entitled to expect in return for the payment of their annual fee is the right to practise dentistry, and the protection which the Board can afford to them in this respect by instituting proceedings against unregistered persons for infringement of the Act. Had the annual fee been payable to the Government, as it easily might have been, dentists would have had little, if any, say in regard to its expenditure; the Board, on the other hand, while carrying out the primary duty of protecting the public, is able to have regard to the interests of dentists in so far as it serves a public purpose connected with the profession of dentistry to do so. Questions are often asked as to how the not inconsiderable income of the Board is expended. This income in 1929 was £43,000, and after paying the fees and travelling expenses of members, the salaries of the administrative staff and office expenses, including the publication of the Dentists Register, £335 was spent on an election of direct representatives of the profession to the Board; £1224 was spent on the prosecution of unregistered persons and of bringing cases of alleged professional misconduct before the Board, and other legal expenses and other items such as income-tax and the cost of prescribed examinations for persons desiring to be registered were provided for. In addition to this, post-registration and post-graduate lectures were given at a cost of £718; £5000 was granted for research; £4000 was spent on instructing the public in the importance of attention to their teeth; £21,000 was allocated for educational grants, and there was a balance for the year of £1434. The grants for research are expended through the Medical Research Council and the Department of Scientific and Industrial Research. Of the money for educational grants, a part is given to assist students educationally well qualified but not in a financial position to take out the curriculum—many of them are the sons of dentists registered under the Act of 1921, who in the old days would have been apprenticed to their fathers—and a part to other students carefully selected from secondary schools. The remainder is spent upon improving the teaching in the dental schools so that students may be as well qualified as possible to attend to the requirements of the public. In addition to this, considerable sums have been granted towards the building of dental schools and to improve their equipment so that the teaching may be given in the best possible circumstances. The memorandum concludes by pointing out that although all this money is primarily expended for the benefit of the public, incidentally the members of the dental profession do benefit considerably thereby.

A MISSION TO CHINA.

SOME years ago the Milbank Memorial Fund made a grant for improving the health of the population in a rural county of China supporting 400,000 inhabitants. The experiment is to last for five years, and is to include public health measures, agricultural extension, industrial education, social surveys, and research in methods of teaching. It

may appear untimely to undertake this task in a period of political crisis, but it is felt by the Chinese leaders of the Mass Education Movement that the experiment may be a foundation for more effective government activities when the situation improves. Hitherto, few public health measures have been put into effect in China, especially in rural districts; no accurate vital statistics exist, but records of sample populations indicate a death-rate of 30 per 1000, and an average expectation of life at birth of about 35 years. The inhabitants of Ting Hsien city, the headquarters of public health activities, are ignorant, poor, and superstitious; social conditions are bad, and in the whole county under experiment there was no one qualified to practise Western medicine when the scheme was initiated. Agricultural and educational work were begun in 1927 under Dr. James Yen, and have made considerable progress; in 1929 public health work was started, a small dispensary and clinics were established at the county seat, and a survey of health conditions and the collection of vital statistics were undertaken. Last spring vaccination against small-pox was introduced, and a preliminary programme for the extension of health services was formulated. Certain specific health problems are now being attacked—notably small-pox, trachoma, tetanus, and gastro-intestinal diseases—and gradually activities will extend to maternity and child welfare, while health education will be continued in the schools and among the general public. Hospital accommodation—necessarily limited at the outset—is to be provided for cases not involving serious operations or chronic conditions; maternity cases will be accepted, however. Research into the purification of water-supplies, protection of food, and disinfection of human fæces used for fertilising purposes will be undertaken. A health centre to be established in Ting Hsien will provide headquarters for the administrative and supervisory staff, a small infirmary of 25 beds, a pharmacy and public health laboratory, an out-patient department, and a lecture room for persons in training. The personnel will include a medical director, an assistant health officer, a public health nurse, a woman doctor to supervise maternity and child welfare work, an educational director, a laboratory worker, and a pharmacist. The infirmary will have a separate staff, including a physician, clinical aides, and nurses. Sanitary inspectors, visiting aides, and midwives will be trained at the centre, and a gradual extension of activities will be made to neighbouring villages. The aim is to make the experiment as economically as possible, in order that similar work may be carried on by the Chinese themselves.

INTERRUPTION OF PREGNANCY IN RUSSIA.

RECENT articles in the *Medizinische Welt* deal with the legalisation of abortion in Russia, which is having its effect on popular opinion in the adjoining countries. In Russia even before the revolution of 1917 abortions were frequent, but after it they became so numerous, and were so often followed by serious illness or death, owing to the conditions of secrecy surrounding the practice, that in 1920 the interruption of pregnancy, apart from medical reasons, was authorised with certain safeguards. The regulations prescribe that the operation may only be performed by a doctor, and in a hospital or officially approved establishment; any person other than a doctor attempting such an operation is liable on conviction to a fine of £50 and a year's imprisonment, extended to five years if the woman dies. In 1926 66 men and 805 women were convicted of this offence. The woman who desires this operation on other than medical grounds appears before a board which decides in the first place if there is any contra-indication; if none, her request may be approved if she is unmarried and workless, unmarried with one or two children, married with more than three children, or an insured woman who is suckling a baby. Other points, such as poor constitution, no private residence, or a husband on military service, may be taken into consideration. The operation must be done during the first three months of pregnancy. Abortions are now tabulated like births; in Leningrad during 1929 the births numbered 39,058 and the abortions 53,512; the birth-rate, for a population of 1,700,000, is 23 per 1000, which is conspicuously high. The deaths after abortion are not separately stated, but it is believed the mortality is higher than after parturition, though complications are decreasing. The chief difficulty is to provide enough doctors and equipment everywhere, especially in the country districts; but that is being done. The motives for the interruption of pregnancy may be found in the high cost of living and a desire to weaken the social prestige of the family, which helped in the early days of the revolution to buttress the old régime. But there are some even in Russia who would prefer to encourage education in preventive measures.

THE SERVICES

ROYAL ARMY MEDICAL CORPS.

Maj. J. M. Pinkerton is granted a temp. commn. in the rank of Capt., and relinquishes the rank of Maj.

The undermentioned Lts. to be Capts. (Temporary Commissions): J. D. Dillon, B. H. H. Tripp, G. de N. M. Somers, J. B. Carrigan, and R. S. de C. Bennett.

Lt. A. H. Weston resigns his commn.

ARMY DENTAL CORPS.

Lt. H. Quinlan to be Capt.

TERRITORIAL ARMY.

Capt. W. T. G. Boul resigns his commn.

Lt. L. F. Richmond (late R.F.A., T.F.) to be Lt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Lt.-Col. J. R. Pooler, having attained the age limit, retires and retains his rank, with permission to wear the prescribed uniform.

INDIAN MEDICAL SERVICE.

Maj.-Gen. F. H. G. Hutchinson retires.

DEATHS IN THE SERVICES.

Lieut.-Col. James Hickman, R.A.M.C., retd., who died on Dec. 18th, qualified with the L.R.C.P., L.R.C.S. Edin. in 1880, and joined the Royal Army Medical Corps two years later. In 1886 he served with the Burmese Expedition (medal with clasp), and in 1892 accompanied the expedition to the Gambia. He was also with the Ashanti of 1895–96 (star), and took part in the operations in Sierra Leone of 1898–99 (clasp). He saw considerable service in the South African War, being present at the relief of Ladysmith, the actions at Colenso and Spion Kop, and the operations on Tugela Heights (medal with clasp, bronze star, and 5th class Medjidie). He was also made Brev.-Maj. He retired in 1904, having reached the rank of Lt.-Col. in 1902.

HOSPITAL SWEEPSTAKES.—The recently formed Sweepstakes Inquiry Committee is sending out 100,000 copies of a questionaire designed to gauge public opinion on the proposal to organise sweepstakes on behalf of English hospitals. Recipients are asked to say if they object to sweepstakes on principle, if they would support an attempt to legalise them, and if they would join a "preliminary hospital sweepstake outside this country" when visiting a country where such things are not illegal.

MODERN TECHNIQUE IN TREATMENT

A Series of Special Articles, contributed by invitation.

CCCXV.

ASPHYXIA FROM COAL GAS.

THE toxic property of coal gas is due to the presence of carbon monoxide (CO). Death from poisoning by coal gas, except with deliberate intent, is comparatively rare, partly because the CO is considerably diluted, and partly because the unpleasant odour of coal gas gives timely warning of its presence. If a mild degree of poisoning is treated without undue delay, the patient is rapidly restored to normal. Employees of the Gas Light and Coke Company who are exposed to the smell of gas in doing repair work are advised to cease work for a spell and go for a short walk in the fresh air when they notice any dizziness, and to drink milk and soda. The theoretical basis of this treatment may not be very clear, but in practice it seems to be effective. There is some evidence that these men acquire a certain degree of immunity which enables them to withstand concentrations of coal gas such as would seriously affect persons unused to this work; also that these workmen show an average longevity greater than the normal throughout the Company. There is certainly no evidence in the contrary direction. CO requires a concentration of 0·5 per cent. in order to be rapidly fatal, while a concentration of two parts per 10,000 can be inspired for a prolonged period without ill-effect.

Patients who are unconscious when first seen provide a more serious problem. CO poisoning is far more common, though less notorious, in countries where charcoal fires are in use, and in districts like Turkey, where houses and harems are heated by charcoal braziers. I have seen many more cases of CO poisoning in parts of Italy and Turkey where no coal gas is used than in London. Since this form of suicide has become fashionable it has attracted much notoriety in the press.

Physical Signs and Symptoms.

CO is poisonous on account of its great affinity for hæmoglobin, whose power to convey oxygen is thus arrested, and anoxæmia ensues. The chief and most important result in serious cases is profound coma. The skin is reddish, the face pink rather than pale. Some authorities state that the red corpuscles are diminished. Cardiac dilatation and irregularity is present, and usually tachycardia; sometimes bradycardia. The pulsation in the neck is visible and violent, and vomiting may take place. Headache, giddiness, nausea, and indigestion are prominent symptoms, also weakness (especially of the lower limbs), fatigue, and drowsiness. Patients may complain of pain in the back and epigastrium, and muscular incoördination and diminution of activity of the five special senses may be noticed.

First-aid.

The first rule is promptly to remove the patient from the cause, or the cause from the patient. In most cases first-aid has been given by a layman before the doctor arrives, but this has not always been inspired by right principles. Those who have to instruct laymen in first-aid classes on this matter would give concrete and definite rules for one who finds a patient poisoned by CO. The following routine is that taught by me:—

Send someone to fetch a doctor, with instructions to explain to him the urgency and character of the case, and to return at once. Someone else should procure an oxygen or, better, an oxygen and CO_2 apparatus at hospital or chemist and obtain an ambulance.

In many cases a gas-filled room must be entered. If so, take two deep breaths and apply a handkerchief, towel, or other material (wetted if possible) to mouth and nose. Seize a stick or umbrella, and go in on all fours or crouching. Some months ago it was stated in a coroner's court that it was a mistake to enter a room on all fours in which coal gas had been recently liberated, on the ground that the poisonous gas was heavy and sank to the floor. The poisonous ingredient is, however, not the heavy CO_2 but CO, which is somewhat lighter than air. The tendency is for coal gas to rise when liberated in ordinary atmosphere, and later to become disseminated by diffusion throughout a room free from draught. Proceed rapidly to the window and break it with whatever implement is available. Then turn off gas tap or, if possible, discover the leak. It is necessary to remember that finding the leak with a lighted match is effectual, but fatal. Drag the patient out into the passage by his heels, and undo tight clothing, with help of bystander. Most important now is the performance of artificial respiration.

Artificial respiration.—If the patient is lying on his face, employ Schäfer's method, which is, generally speaking, the best method of artificial respiration. If the patient is lying on his back, and an assistant is present to hold the tongue out, do not waste time in turning him over if there be any difficulty in doing so, but perform artificial respiration by Sylvester's method. As a rule attempts at artificial respiration are abandoned too soon. They should be continued for several hours, changing the operator as he gets exhausted. Artificial respiration should not be started if the patient is breathing moderately well, as it will retard rather than help his respiration; nor should it be continued after his breathing is established. On the other hand, artificial respiration should not be abandoned because the patient appears to be dead. If he is not, this lack of perseverance may kill him. After artificial respiration has been successful in restoring life the following directions are important:—

Cover up the patient and keep him warm with hot-water bottles and wraps, protecting him from cold draughts. When he is conscious enough to swallow, and only then, give him hot coffee or tea. It is most important to give him only a few drops with great care at first, to test his ability to swallow.

When he is removed to a hospital or elsewhere the transport should be effected with the least possible disturbance to the patient. Rest is essential.

Treatment Other than First-aid.

Oxygen.—The main point of treatment is to get oxygen into the blood. When the patient has started breathing a suitable inhaler, to give 5 per cent. of carbon dioxide, should be procured if possible, since this gas stimulates the respiratory centre. Personally, I have found the hypodermic injection of oxygen in large quantities over limbs, buttocks, back, and abdomen, producing extensive emphysema of the skin, to be efficacious and safe. An advantage is that it can be carried out rapidly at the same time as all other measures are being adopted. The oxygen thus injected subcutaneously is rapidly absorbed and leaves no ill-effects. It must be remembered that the amount of O_2 which can be absorbed this way is small compared to that which can be taken in by the normal route—the lungs. Fresh air and artificial respiration as stated above are therefore of paramount importance. Some of the few who have given a fair trial have not found benefit but no one has found it harmful. On the other hand, most drugs which have been tried have done more harm

than good—e.g., stimulants, strychnine, camphor, and ether.

Blood transfusion and bleeding may be used together, but fail to do much good after the first hour.

The pulmotor or lungmotor apparatus are sometimes useful in skilled hands, but usually less efficacious than continued artificial respiration. In any case this should be used pending the arrival of the other two.

Contra-indications.

Stimulants are contra-indicated. It is not wise to dash cold water on the patient; you will incur the responsibility of causing the fatal attack of pneumonia which may result. The patient should not be allowed to stand or sit up, and any form of violence should be avoided. Time should not be wasted, since prompt treatment is the most important factor in recovery.

Medical Officer to the Gas Light and Coke Co.

MEDICINE AND THE LAW.

Unauthorised Autopsy.

UNDER this heading the *Solicitors' Journal* has noted an interesting Canadian case, recently reported, in which a plaintiff had certainly a genuine grievance. He engaged a firm of undertakers to make all preparations and arrangements for the burial of his dead wife, the body being given into their charge for this purpose. He subsequently discovered, so at least he alleged, that the undertakers had allowed a surgeon to enter their premises and, without any permission from himself, to conduct an autopsy and remove from his wife's body a portion of the anatomy. He claimed damages for this action, both from the undertakers and the surgeon, on the ground of the mental anguish which he had naturally suffered thereby. The court held that the action, being solely for the recovery of damages for mental anguish, was not maintainable. As our contemporary points out, English law has always made a difficulty about recognising property in a human corpse. Thus the plaintiff, with whose feelings everyone will sympathise, was left without remedy.

The point is perhaps worth elaborating. The judges have held, more than once in England, that there is no property in a corpse. Executors, however, are prima facie entitled to custody of a deceased person's body for the purpose of performing their duty of burial. It is conceivable also that there might be property in a mummy. If a corpse is stolen, an indictment would lie for stealing the shroud or wrappings round the body; the property in the shroud after burial remains in the person to whom it previously belonged. At common law a man could not legally dispose of his body after death, but the Anatomy Acts have made a breach in this principle. Section 8 of the Act of 1832 allows a man, either in writing or verbally before two witnesses, to direct that his body be examined anatomically; dissection may then follow (subject to certain conditions) unless the surviving husband or wife or the nearest known relatives require interment without such examination. Section 7 of that Act, not cited by our contemporary, would have had some bearing if circumstances similar to those in the Canadian case had occurred in England. The Section says it shall be lawful for any executor or other party having lawful possession of the body of any deceased person, *and not being an undertaker or other party intrusted with the body for the purpose only of interment*, to permit the body to undergo anatomical examinatio unless either the deceased had expressed a desire t the contrary or the surviving husband or wife or an known relative of the deceased shall require the bod to be interred without such examination. The word cited in italics above convey the implication that th action of the Canadian undertakers, if it had take place in England, would have been unlawful. Ther might thus have been a breach of duty even if th resultant damages still presented legal difficulty.

Foreign-made Surgical Instruments: Indication of Origin.

Proceedings were taken by the Board of Trad lately against a surgical manufacturing compan on a charge of having failed to indicate in its catalogu which of the items set out therein were of foreig manufacture. This was an alleged infringement o the Merchandise Marks Act, 1926, which has, b successive Orders in Council, been applied to variou articles. Part IV. of the large Merchandise Mark (Imported Goods) No. 4 Order, 1928, made two year ago on the application of the Surgical Instrumen Manufacturers' Association, applied the Act t surgical, medical, dental, and veterinary instru ments made wholly or mainly of metal and to al surgical, medical, dental, and veterinary appliances except artificial eyes. Evidence was offered that a Mayo's needle holder, selected by reference to the catalogue, had been ordered from the defendant company, that there was no description of the origin of articles in the catalogue, and that the article actually supplied was of foreign origin. There was similar evidence of the ordering of another article from the catalogue; the article supplied proved to be of German origin and the purchaser sent it back with an inquiry whether it was of British or foreign manufacture; it was then returned with a small tab attached to it bearing the word "Foreign." The defence suggested that the order was on behalf of a medical practitioner who belonged to the Indian Medical Service, and that therefore the Act did not apply as the article was for dispatch and use abroad; but, as Section 2 of the Act is aimed at sale or exposure for sale in the United Kingdom, this was an unpromising loophole. As regards other articles, some were genuinely British, others were admittedly unmarked, and as to these the company pleaded guilty. The magistrate inflicted various fines with costs; he said the Act had been infringed and the company had pretended that the bulk of its goods were of British manufacture when in fact they were not.

The object of the Act is "to require an indication of origin to be given in the case of certain imported goods." Its supporters claim that this enables purchasers to "buy British" and thus promotes employment in this country. Its critics maintain that the "indication of origin" merely gives a gratuitous advertisement to a cheap or desirable foreign-made article. In the recent proceedings it appeared that the Mayo's needle holder was priced at 10*s.* 6*d.*, at which price it could not possibly be British made, and that the price for the same article, if made in Britain, would be not less than a guinea. This raises a political issue on which the magistrate was careful not to express an opinion.

AN ITALIAN CONFERENCE ON CANCER.—The Lega Italiana per la Lotta contro il Cancro is holding its second national congress at Bologna on Jan. 4th and 5th, 1931. The congress will coincide with the opening of a centre for the study and treatment of cancer. The secretary may be addressed at the Clinica Medica, Policlinico S. Orsola, Bologna.

SPECIAL ARTICLES

THE CHEMISTRY OF MUSCULAR CONTRACTION.*

By Prof. Otto Meyerhof, LL.D.,

DIRECTOR OF THE PHYSIOLOGICAL INSTITUTE (KAISER WILHELM INSTITUT FÜR MEDIZINISCHE FORSCHUNG) AT HEIDELBERG.

To begin with I must review briefly the chemical processes involved in the performance of work by a muscle. The following description might be given of the course of events involved in a muscular twitch.

Coincident with contraction lactic acid is formed from glycogen, giving rise to about 385 calories of heat per gramme of lactic acid. With oxidative recovery the lactic acid disappears. It is not all burned, but a coupled reaction occurs in which a proportion, generally four-fifths, is resynthesised, the remainder being oxidised. Possibly none is oxidised, but an amount of carbohydrate equivalent to one-fifth of the lactic acid is burnt, while all the lactic acid becomes glycogen. It is, therefore, safer to speak of the ratio of the total lactic acid removed to the lactic acid equivalent oxidised. This figure I have called the "oxidative quotient." According to measurements made in my laboratory, the heat of combustion of glycogen (referred to one gramme of the hydrate in aqueous solution) is 3782 calories. One-fifth of this value (757 calories) is the amount of heat we should expect to accompany the production and oxidative removal 1·0 g. of lactic acid. Since the production alone accounts for 385 calories, the remaining 372 calories are to be looked for in the recovery phase. Thus the heat of recovery should be approximately the same as the heat of activity, a result which was arrived at by A. V. Hill several years ago.

This oxidative quotient is a figure of general significance in muscle metabolism and is not limited to the process of recovery after fatigue. For instance, a muscle resting in nitrogen produces lactic acid steadily; in oxygen no lactic acid accumulates. The lactic acid formed per hour in the absence of oxygen is, however, three or four times as great as could be burned by the oxygen which would have been used in the same time in aerobic conditions. Thus it is evident that a continuous cycle of reactions takes place, resting metabolism giving rise to three or four molecules of lactic acid which are continuously reconverted by respiration, while one equivalent of lactic acid is burned. The lactic acid which accumulates in the resting anaerobiosis is found to disappear subsequently in oxygen according to the same oxidative quotient. While this conformity suggests that we have here a correct interpretation of Hill's myothermic data in terms of chemical reactions, nevertheless recently discovered facts are forcing us to modify some essential details. In the first place, we have to abandon the idea that lactic acid itself plays a rôle in the mechanism of contraction, an idea which—although never considered a coercive conclusion of the thermodynamics of contraction—has nevertheless been a great favourite.

The Part Played by Phosphagen.

We are entering a hypothetical field if we proceed from purely thermodynamic considerations to a more definite representation of the physical and chemical processes involved in activity. Nevertheless, I should like to venture this step here, because it enables me to discuss some phenomena of great interest, although the part which they play in the mechanism of contraction is somewhat obscure. Difficulties are met at the beginning in attempting to explain the 385 calories of heat produced per gramme of lactic acid formed in the muscle (the so-called caloric quotient), because the difference between the heats of combustion of dissolved glycogen and dissolved lactic acid is only 180 calories. Part of the lactic acid is neutralised by the proteins of the muscle, liberating 140 calories per gramme of lactic acid thus neutralised; but part is neutralised by the phosphate and bicarbonate—a reaction only slightly exothermic—so that not more than 100 calories on the average may be attributed to the neutralisation process. This value may be reached by direct experiments in which acids such as valerianic are allowed to diffuse into a muscle. In such cases about 10,000 calories of heat have been observed per gramme-molecule. A similar figure of 9400 calories has recently been obtained by Dr. Stella (in Prof. Hill's laboratory) for the heat of neutralisation of carbonic acid allowed to diffuse into a muscle. Thus, if we include the cleavage heat of glycogen, about 280 calories would be accounted for, leaving the origin of the remaining 100 calories unknown.

Now there is in fact another reaction known to occur simultaneously which, in vitro, produces about the required heat. Although it is still a matter of dispute whether the heat is liberated to its full amount in the living muscle, I cannot avoid discussing further this interesting possibility. Early in 1927 the Eggletons published the discovery that the greater part of the "inorganic" phosphate of resting muscles was actually present in the form of an unstable compound which they called phosphagen and which is split under the influence of muscular activity, while it is resynthesised during oxidative recovery. This compound was shown by Fiske and Subbarow to consist of phosphate and creatine. In coöperation with Dr. Lohmann, Dr. Nachmansohn, and lately Dr. Lipmann and Dr. Lundsgaard, I have thoroughly investigated the behaviour of this compound chemically and physiologically. For different kinds of activity and under different conditions the amount of phosphoric acid derived from phosphagen may be compared with the simultaneously produced lactic acid. In the course of anaerobic fatigue this quotient rapidly decreases from an initial value of three or four down to far below one, and even to zero—that is, in extreme fatigue hardly any creatine-phosphoric acid is split at all while the lactic acid production is still more or less proportional to the muscular tension produced. Moreover, this quotient is strongly affected even in fresh muscles by different influences—e.g., it is low from the beginning in curarised muscles and after nerve degeneration. If curarisation is effected by quaternary ammonium bases, the quotient may fall to as low as one-eighth of the normal value.

It is found, in fact, that the extent of phosphagen breakdown varies in strict parallelism with the speed of the excitation processes, and not only under the influence of curare and of nerve degeneration, but also in normal muscles at different temperatures and in different states of fatigue. Thus at 8° C. both speed of

* Abstract of a series of four lectures given at University College, London, in March, 1930.

excitation and relative phosphagen breakdown have half the value characteristic of 24° C.; in a similar manner the slow muscles of the toad differ from the rapid muscles of the frog. Figs. 1 and 2 may help to demonstrate the change in phosphagen breakdown relative to lactic acid production. The restricted decomposition very noticeable in the case of trimethyl-octylammonium iodide corresponds to an equally

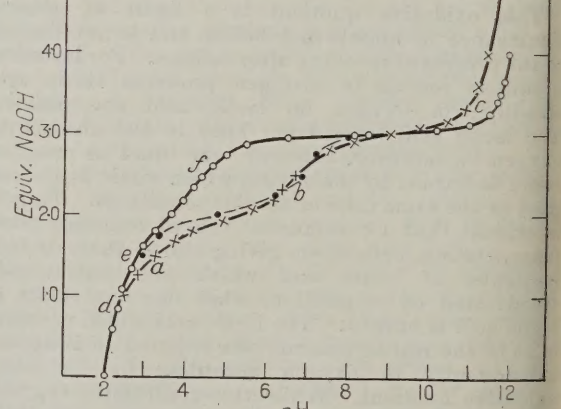
strong reduction in the speed of excitation (the chronaxy is 30 times longer than normal). But the breakdown was determined in these cases by estimations before and after activity. A detailed investigation of the time course of the reaction, however, shows that at the height of prolonged contraction much more phosphagen is split, about one-third of the quantity decomposed undergoing anaerobic restitution in the 20 seconds following relaxation. Moreover, the absolute quantity thus restored is nearly the same in cases where there is a considerable restriction of the total decomposition. During each single contraction, therefore, more phosphagen is split than can be accounted for by the final determination; indeed, with far-advanced fatigue the breakdown is almost entirely reversed anaerobically, a fact which seems to be of very essential importance.

As mentioned before, the hydrolysis of creatine-phosphoric acid is an exothermic reaction, yielding about 120 calories per gramme of phosphoric acid liberated. In 1927, in a paper read before a meeting of the British Medical Association, I voiced the opinion that this heat approximately covered the shortcoming in the caloric quotient. Later on, however, doubts arose as to the reality of the "breakdown" and "resynthesis" of phosphagen in the living muscle. I cannot now go further into these difficulties, which are chiefly connected with the anaerobic resynthesis, but I should like to describe two series of experiments carried out in my laboratory and not yet published which leave us in no doubt that the hydrolysis of creatine-phosphoric acid occurs in muscle just as in vitro and that it is of the utmost importance in the contraction mechanism.

The first series of experiments, which I made in collaboration with Dr. Lipmann, shows in a striking manner the reality of the hydrolysis. This hydrolysis, if carried out at a reaction only slightly acid, leads t the production of basic equivalents, because th guanidine group of creatine is very much stronge than the third valency of the phosphoric acid liberate at the same time (Fig. 3). At pH 6 the change i so marked that the hydrolysis of one molecul produces nearly one basic equivalent. At pH 7 th effect is considerably less, and at pH 8 it is vanishingl small. This liberation of base enables us to demon strate the hydrolysis of phosphagen in a living muscl suspended in an atmosphere of nitrogen and carbo dioxide. In such a case, when bases are formed th muscle takes up carbon dioxide from the gas around and when acids are formed carbon dioxide is expelled These changes can be followed by measurements o the partial pressure of carbon dioxide in th surrounding gas, and we find that when breakdow of phosphagen occurs, carbon dioxide is, in fact, take up by the muscle and the more so the nearer it is t pH 6—i.e., in a pure atmosphere of carbon dioxide At this reaction, moreover, the hydrolysis of creatine phosphoric acid is accelerated and lactic aci production checked. If the degree of alkalisation i determined from the uptake of carbon dioxide b means of the Henderson-Hasselbalch equation, it i found to be in conformity with the measured cleavag of creatine-phosphoric acid, after allowing for th lactic acid formation. Fig. 4 shows a curve of thi nature, in which the uptake of carbon dioxide i plotted downwards and the output upwards from th base line. The peculiar result is observed that th muscle under higher pressures of carbon dioxid actually grows more alkaline during the first hundre or two hundred twitches. It is clear that as long a the reaction of the muscle is displaced towards th alkaline side or remains unchanged; after activity, heat of de-ionisation of protein cannot appear. Fo

FIG. 3.



The titration curves of creatine-phosphoric acid, before (*d*, *e*, *f*) and after (*a*, *b*, *c*) hydrolysis.

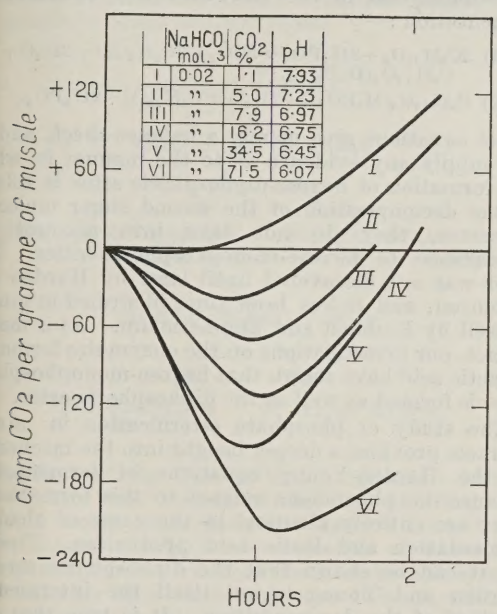
the present I should like to assume that in the earlier stages of fatigue the heat of hydrolysis of creatine-phosphoric acid acts, so to speak, as a substitute, whilst the heat of de-ionisation of protein gains prevalence in the later stages. Just this gradual substitution of one reaction by another may have the consequence that the heat appearing per unit of lactic acid formed will remain approximately constant or decrease very slightly with increasing fatigue. It seems that the changing of pH in the course of

contractions is not an essential part of the mechanism, but the breakdown of phosphagen is, nevertheless, of primary importance, as is shown by the recent experiments of Lundsgaard in my laboratory.

These experiments, perhaps even more convincing and exciting than those just considered, are leading to the following conclusions: 1. The formation of lactic acid during activity is a process only indirectly connected with the mechanism of contraction. 2. The hydrolysis of creatine-phosphoric acid has an importance as an energy-producing reaction equal to the formation of lactic acid.

According to Dr. Lundsgaard's communication published from Copenhagen, muscles poisoned with iodoacetic acid can perform a series of contractions without giving rise to any lactic acid, whereas phosphagen is broken down at an enhanced rate.

FIG. 4.

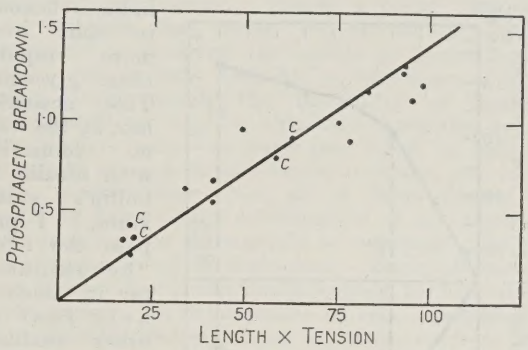


ıe uptake and discharge of CO_2 by muscles suspended in CO_2–N_2 mixtures and stimulated three times per minute. In all cases the muscle tends first to become alkaline.

Then the phosphagen is used up the muscle goes into gor. The quantitative investigations have been rried out by Dr. Lundsgaard in my laboratory at eidelberg, and I should like now to quote some facts hich have been proved in the meantime.

With an adequate degree of poisoning a frog muscle eighing about 1·0 g. can develop, under strictly aerobic conditions, about 30 kg. of tension in a ries of twitches (i.e., about one-quarter of the rmal performance) without giving rise to any lactic id. The phosphagen breakdown is strictly proporonal to the work performed. Taken as a whole, e inorganic phosphate is not increased in amount, y phosphate liberated being afterwards esterified the Harden-Young hexose-diphosphate. In point fact the heat of hydrolysis of phosphagen is just fficient to account for the energy liberated by the uscle because, per unit of tension, three or four times many mols of phosphagen are decomposed as ctic acid would otherwise be formed. According to e foregoing figures the heat per unit of tension ngth would, therefore, have the usual value. The proximate constancy of the isometric coefficient phosphagen in these muscles, and the agreement with the values determined for the heat of hydrolysis, may be seen in Fig. 5. The tension developed is plotted along the abscissa, and phosphate liberated per gramme of muscle along the ordinate. The continuous line is calculated from lactic acid experiments for the same amount of energy and tension. It must remain an open question whether the phosphagen breakdown and lactic acid formation in

FIG. 5.



Showing the strict proportionality between energy liberation and phosphagen breakdown in muscles poisoned with iodoacetic acid and stimulated with a series of single shocks (isometric contractions). c = Curare.

normal muscles must be dealt with as two completely separate energy-producing processes, or—as I am rather led to believe—the lactic acid formation supplies the energy for a continuous resynthesis of phosphagen at the moment of contraction. Indeed, Dr. Lundsgaard's experiments show that in a muscle poisoned with iodoacetic acid there is no anaerobic resynthesis and that the amount of energy produced, or work done, is unequivocally determined by the amount of phosphagen breakdown. The results of these experiments warn us that we must not be too rash in employing the chemical processes so far known to us for building up a theory of muscular contraction.

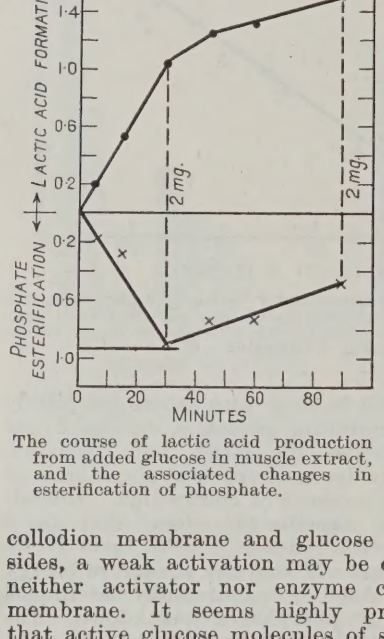
Study of the Lactic Acid-forming System in Vitro.

I should like to recall the enormous importance which Buchner's separation of zymase from yeast cell had for the chemistry of fermentation. I was able to show a few years ago that we may even succeed in isolating the lactic acid-forming system from muscle and setting it to work in a homogeneous solution. This system may be separated into its components, and the isolated enzyme may then be concentrated to a considerable degree and freed from accompanying substances by Willstätter's adsorption methods—particularly adsorption on aluminium hydroxide and elution by phosphate. By proceeding in the proper way extracts of muscles are obtained free not only from all structural constituents but also from carbohydrate. They are rich in enzyme, so the behaviour of various added carbohydrates, as well as the different phases of the acid production, may be studied separately and in detail. It is a further advantage of the study of lactic acid formed in solution that we are not limited to wearisome chemical determinations, but may effect the measurement of the lactic acid by means of the exact and comfortable manometric methods of Warburg.

It is a striking fact that glycogen, starch, and their various polysaccharidic hydrolysis derivatives, such as amylose, amylopectin, and the so-called hexosanes, are

all converted into lactic acid by the muscle extract with equal facility and speed. On the other hand, the hexoses are attacked very slowly if at all. An activator may be obtained by autolysing yeast and precipitating the yeast extract with 50 per cent. alcohol. The addition of this activator to a muscle extract allows the fermentable hexoses to be glycolysed with great rapidity. By itself this activator can do nothing, but its addition to the muscle extract induces hexoses to split even more rapidly than glycogen. This activator has, by the way, no connexion with insulin or Collip's glucokinin. I propose the name "hexokinase" for it, since it acts just as other auxiliary enzymes designated as kinases. We know very little about the mechanism of this activation. If the enzyme is separated from the activator by a collodion membrane and glucose is added to both sides, a weak activation may be observed, although neither activator nor enzyme can penetrate the membrane. It seems highly probable, therefore, that active glucose molecules of short existence are formed and react with the enzyme. At any rate the transformation of ordinary glucose into such an active form does not depend on the structure of the cell, for the yeast activator as well as the muscle extract are structureless. In a concentrated aqueous extract of rabbit muscle a slow lactic acid production from glucose takes place, even without the addition of an activator. In a recent paper, McCullagh and Case, of Hopkins's laboratory, mentioned that they could effect the splitting of glucose only with suspensions of mammalian tissues, not with tissue extracts free from cells. Personally I am inclined to think that it depends upon special technical conditions whether or not the factor which activates hexoses may be separated from the structure of the cell.

FIG. 6.



The course of lactic acid production from added glucose in muscle extract, and the associated changes in esterification of phosphate.

Fig. 6, taken from a series of experiments carried out some years ago, shows the change which a certain quantity of glucose added to an extract undergoes in the presence of hexokinase. The lactic acid formed is plotted upwards and the phosphate esterified is plotted downwards; both are shown on the same scale. It is apparent that the lactic acid is formed at the beginning at a very considerable rate, while simultaneously phosphate is esterified. Within 30 minutes the whole 2 mg. of glucose added are consumed, partly by formation of lactic acid and partly by esterification with phosphate. As the symmetry of the initial parts of both curves shows, the esterification of phosphate is approximately equimolecular with the lactic acid production. When, however, all the sugar is used up, a slow period follows in which the formation of lactic acid is accompanied by a reappearance of phosphate. Direct analyses sho that hexose-mono- and diphosphoric esters ar formed during the first period and broken dow during the second. Since the rapid period lasts a long as sugar and phosphate are available, the yiel of lactic acid in this period is determined in th presence of excess of sugar by the amount of phosphat available. Before approaching an interpretation c these phenomena I would first point out the complet analogy existing between these two phases of enzymati formation of lactic acid and the time course o alcoholic fermentation by yeast extracts. Here, too according to the fundamental discovery of Harde and Young, the same two phases are observable a rapid fermentation phase during which phosphat is esterified to an extent proportional to the productio of carbon dioxide; then a slow phase which i characterised by the fermentation of the hexos esters formed during the first phase. These fact are summarised in the Harden-Young equations c fermentation:—

(1) $2C_6H_{12}O_6+2H_3PO_4 \rightarrow 2CO_2+2C_2H_5OH+2H_2O+C_6H_{10}O_4(H_2PO_4)_2$.

(2) $C_6H_{10}O_4(H_2PO_4)_2+2H_2O \rightarrow C_6H_{12}O_6+2H_3PO_4$.

These equations give merely a balance-sheet, and d not supply any evidence as to the manner in whic the formation of hexose-diphosphoric ester is relate to the decomposition of the second sugar molecul Moreover, they do not take into account th appearance of hexose-monophosphoric ester. Thi ester was not discovered until later by Harden an Robinson, and it has been since identified in musc as well by Embden and Zimmermann. As a matte of fact, our investigations on the enzymatic formatio of lactic acid have shown that hexose-monophosphori ester is formed as well as the diphosphoric ester.

The study of phosphate esterification in musc extracts provides a deeper insight into the mechanis of the Harden-Young equations of fermentatio because the phenomena related to this formation c ester are entirely identical in the cases of alcoholi fermentation and lactic acid production. First c all, it can be shown that the diphosphoric ester c Harden and Young is not itself the intermediar product of the decomposition. It is true that it i attacked even by such enzyme solutions as ar incapable of decomposing hexoses or polysaccharide —e.g., by stale enzyme solutions or such as have bee heated to 38°. But while the ability to fermen hexose-diphosphoric ester is more permanent than th ability to split pure carbohydrates yet the rate c fermentation is much less. It may, in fact, be show in various ways that an unstable ester arises as a intermediary product of carbohydrate cleavag This ester is partly decomposed and partly changed t the Harden-Young ester—a process of stabilisatio But the unstable ester is a hexose-monophosphori ester. We believe this because the biological hexos monophosphoric esters behave in quite a differen way from the diphosphoric esters in enzymati cleavage. The diphosphoric ester is relatively slowl transformed, and gives rise to equimolecular quantitie of lactate and phosphate. The monophosphori esters, on the other hand, are decomposed ver rapidly at first; exactly as rapidly as sugar. At th same time there is no formation of phosphate; on th contrary, there is a disappearance of inorgani phosphate from the solution. Part of the est decomposes into lactic acid and part takes up th liberated phosphate—and more besides—and becom hexose-diphosphoric ester. When all the mon phosphoric ester is used up, the rate of lactic aci

formation falls off, and now the liberation of lactic acid is accompanied by equimolecular quantities of phosphate.

The Harden-Young Equations Applied to Muscle Extract and Yeast.

It can be proved by the addition of fluoride to this system that as a matter of fact hexose-monophosphoric ester is transformed directly into hexose-diphosphoric ester. To be sure, the diphosphoric ester appearing here is not the Harden-Young ester; to that question I shall return later. This observation, as well as a series of others, is leading plainly to the conclusion that hexose-monophosphoric ester is the intermediate body in the carbohydrate cleavage, and we must regard the Robison ester as the first step from the actual intermediate towards stabilisation. The true intermediate cannot accumulate because of its instability. Provided with this knowledge, we can formulate the Harden-Young equations afresh, both for muscle extract and for yeast.

$$\underset{\text{A}}{2C_6H_{12}O_6+2H_3PO_4}$$

$$\downarrow$$

$$2C_6H_{11}O_5(H_2PO_4)+2H_2O$$

$$\swarrow \qquad \searrow$$

$$2CO_2+2H_2O+2C_2H_5OH+C_6H_{10}O_4(H_2PO_4)_2 \qquad 2C_3H_6O_3+2H_2O+C_6H_{10}O_4(H_2PO_4)_2$$

$$\underset{\text{B}}{2C_6H_{10}O_4(H_2PO_4)_2+2H_2O}$$

$$\swarrow \qquad \searrow$$

$$2CO_2+2C_2H_5OH+2H_3PO_4 \qquad 2C_3H_6O_3+2H_3PO_4$$

The first of the Harden-Young equations is here vided into two stages, in the first of which the stable hexose-monophosphoric ester is formed and the second of which two molecules of it react in ch a manner that one becomes a diphosphoric ester d the other forms two molecules of lactic acid. I ve not so far mentioned that the analogy between tic acid formation in muscle and the alcoholic mentation is also demonstrated by the fact that e dialysable, thermostable co-enzymes necessary the two processes are interchangeable. They ve the same chemical properties, so far as these ve been investigated. Although we do not know t the exact part played by this co-enzyme, it is obably required for the esterification process licated in the first equation of fermentation. It d already been proved by Harden that the hydrolysis hexose-diphosphoric ester does not require the sence of the co-enzyme. According to the view Harden and Young the hydrolysis of hexose-hosphoric ester must precede the fermentation of hexose, the latter being esterified again in accord-e with the first equation. It has been shown, wever, that hexose-diphosphoric ester can be mented in solutions extremely poor in co-enzyme, l it can be converted into lactic acid by muscle racts incapable of glycolysing sugar or glycogen uted extracts or extracts which have been heated 37°). It seems, therefore, that the diphosphoric er must be fermented direct without any previous drolysis, and this fact is expressed in the modified nd equation above. Without doubt the drolysis assumed by Harden and Young takes ce, but I regard it rather as a side reaction.

Objections have recently been made by members of Harden's laboratory to this modification of Harden's equation. It is claimed that hexose-monophosphoric ester must be considered as an intermediate product not only of the formation of the diphosphoric ester but also of its decomposition. This is surely true; I believe that the modified equations only represent a kind of ideal case, freed from the disturbances of accessory reactions. In fermentations by dry yeast further complications are added, such as the formation of the trehalose-monophosphoric ester recently discovered by Robison. Taking a broad view, we must suppose that sugar, by esterification with phosphate, is rendered susceptible to fermentative attack, and is thus brought to decompose. In a certain configuration the instability of hexose-monophosphoric ester is obviously especially great. This reactive ester—or such part of it as escapes immediate decomposition—tends to change into more stable modifications. Not all of these appear in the living muscle; the coördination of esterification and breakdown is presumably so complete that we find always one and the same ester. This coördination must be imperfect in the muscle extract, for here other esters appear. In consequence of this coördination, no measurable decomposition of hexose ester occurs in a muscle as a result of activity when a large quantity of lactic acid is suddenly formed. On the contrary, a temporary increase of hexose-monophosphoric ester is more likely to be observed in such conditions, perhaps because the esterification process is somewhat faster than the glycolysis. Precisely on account of this excellent coördination of the separate reaction phases, the actual chemistry of the reaction cannot be recognised in living muscle, but only in the separated enzyme solution.

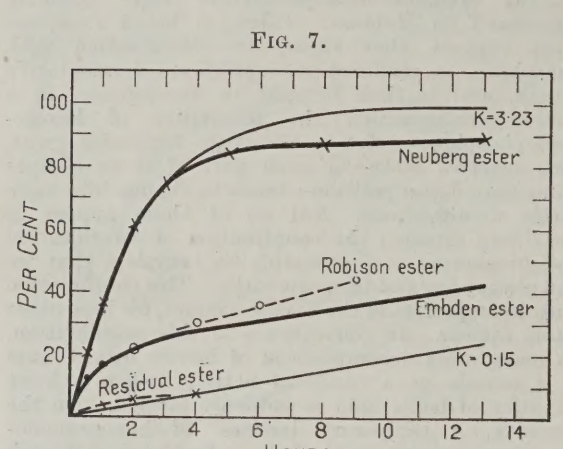
Further similarities between the glycolytic function of muscle and the fermentative function of yeast are revealed by the similar action of certain chemical substances on the two processes. For example, Harden showed that arsenates strongly accelerate fermentation in extracts of yeast on account of quicker splitting of the hexose-diphosphoric ester. Various experiments in my laboratory have convinced me that this is the only way in which arsenates accelerate fermentation in widely differing circumstances. For instance, the fermentation of glycogen proceeds at a three- or a four-fold rate in the presence of arsenate, because in the fermentation of glycogen in the absence of arsenate three or four hexose-phosphoric ester molecules would accumulate per molecule of hexose fermented. In muscle extract arsenate has exactly the same effect. From these and other analogies we must conclude that esterification with phosphate is the common initial stage of both the alcoholic fermentation and the formation of lactic acid and, moreover, that the same three-carbon compound is most probably the next stage in the decomposition. According to Neuberg's and Dakin's theories this product may be methylglyoxal; most tissues contain an enzyme capable of converting methylglyoxal into lactic acid. These theories have been recently confirmed by Ariyama, who obtained methylglyoxal from hexose-phosphoric ester by means of tissue extracts. Neuberg has observed a similar action of dry yeast preparations. But from this point onwards there must obviously be a separation in the courses followed by the yeast enzyme system and the muscle enzyme system. Whatever may be the differences in detail, there is a surprising similarity between the two kinds of anaerobic carbohydrate katabolism in cells so different as those of a facultatively anaerobic micro-organism

and those of the muscles of the higher animals. This agreement leaves no doubt that the metabolic processes, for all their striking variety, are based on definite and uniform biochemical laws.

The Phosphoric Esters of Muscle.

The physiologist Embden, of Frankfurt, assumed that of the acid-soluble phosphate in muscle only one compound took a share in the formation of lactic acid. He designated it "lactacidogen." It was believed to

FIG. 7.



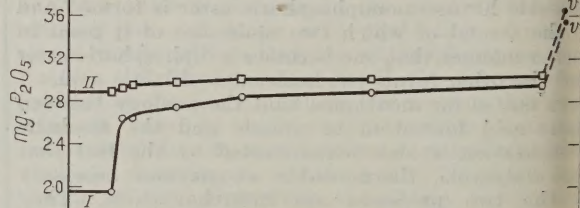
The hydrolysis of certain hexose-phosphoric esters in normal hydrochloric acid solution at 100° C. Such curves reveal the composite nature of some of the natural esters.

be closely related to, or even identical with, the Harden-Young hexose-diphosphoric ester of fermentation, but in muscle it was said to split into equimolecular amounts of lactate and phosphate. In the place of this one phosphoric ester we have now three separate groups of compounds playing different parts in the metabolism of activity. Their only point of comparison lies in the fact that from them all orthophosphate may be liberated enzymatically. In only one respect is the older conception justified: it is that we must consider a hexose-phosphoric ester to be the intermediate product in the formation of lactic acid from glycogen.

We will begin by considering this group of hexose-phosphoric esters. All of them can arise in, and can be fermented in, either yeast-press juice or muscle extract. A very simple method serves for the distinction of the known hexose-phosphoric esters and for the detection of new ones, a method which K. Lohmann has worked out in my laboratory. The rate of hydrolytic liberation of phosphate in a protein-free solution at 100° C. in the presence of normal hydrochloric acid is measured. In the case of a single pure ester the curve obtained is that of a monomolecular reaction with a certain characteristic constant. The course of such an acid hydrolysis is shown in Fig. 7 for the hexose-phosphoric esters already known; the upper heavily traced curve refers to the Neuberg ester obtained by the partial hydrolysis of the Harden-Young diphosphoric ester. In this case there is at first a very rapid hydrolysis, and when 80 per cent. of the phosphate present has been split up there is a sudden decrease in the rate. When the velocity constants of this hydrolysis are calculated, two values are obtained, one of which is applicable to the first 75 per cent. and the other—20 times smaller—is applicable to the last section of the curve. Robison's ester (from yeast extract) or Embden's ester (from fresh muscles) behave like the Neuberg ester only for the first 10 per cent. of the hydrolysis then the velocity constant changes to a value only one-tenth as large. It can be shown in numerous ways that these esters are mixtures, consisting mainly of two components. The more easily hydrolysed component is a ketose ester, the other contains aldose. The two components may be separated from each other, for example by hydrolysing the ketose ester and preparing the aldose ester from the more resistant residue. The lowest curve in Fig. 7 was obtained from the aldose component isolated in this way. It is seen to have a perfectly steady hydrolysis constant. Other methods of examination have all led to the same result—namely that the Embden ester and the Robison ester are made up of about four-fifths aldose and one-fifth ketose, whilst the Harden-Young ester, and the Neuberg ester obtained from it, contain four-fifths ketose and one-fifth aldose. Moreover, these esters have always the same composition and arise whether glucose or fructose is the initial body undergoing fermentation. Some time ago Robison and Morgan achieved a similar separation of the components of the Robison ester by fractional crystallisation of the brucine salt, whilst Pryde and Waters defined the aldose and ketose components of Embden's ester in the same way as we did. The kinetics of breakdown of these esters by the lactic acid-forming enzyme are completely alike, a fact which points to close relationship or to the ease with which each of them may be converted into the other.

The hydrolytic method, however, not only permits a characterisation of the known esters and their distinction without chemical methods of separation; it also leads to the discovery of new esters. These newly found esters appear as intermediate products not only in the transformation of genuine carbohydrate

FIG. 8.



The hydrolysis of the complex phosphates of muscle by N HCl at 100°. Curve I, fresh muscle extract. Curve II, autolysed muscle extract. The rapidly hydrolysing component present in the fresh extract is pyrophosphate.

but also as products of the esters already known. They may accumulate if glycolysis is inhibited in certain ways—e.g., by means of fluoride. Embden was the first to recognise that when fluoride is added to minced muscle an accumulation of hexose-phosphoric ester—which he thought to be the Harden-Young ester—takes place, while the formation of lactic acid is inhibited. The investigations by means of the hydrolysis method carried out by Dr. Lohmann demonstrate that, while some Harden-Young ester is formed, the main product is a hexose-diphosphoric ester of entirely different characteristics. Its hydrolysis constant is 20 times smaller, and its salts are much more soluble. This "fluoride ester," as we may provisionally call it, arises not only in the

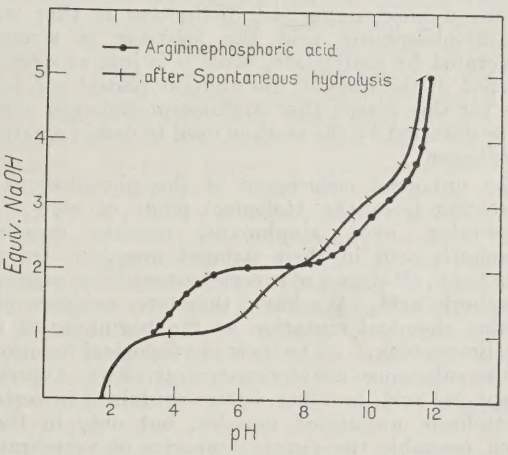
transformation of free carbohydrate but also in the transformation of the Harden-Young ester, in the presence of fluoride.

Pyrophosphate of Muscle and its Hydrolysis.

All these compounds are, from a purely biological point of view, only of secondary interest, for they appear with such variety only in aqueous extracts of cells, not in the living muscle itself. It is quite different, however, with the next phosphorus fraction we shall consider. Embden described several years ago a method for the estimation of "lactacidogen" which consisted in measuring the increase in inorganic phosphate content which takes place in muscle tissue when incubated in the presence of bicarbonate at 42°. But Lohmann's investigations have shown that the overwhelming part of the phosphate liberated during this autolysis does not take its origin from a hexose-phosphoric ester and has no direct relationship with lactic acid formation. He found it to be derived from the pyrophosphate of the muscle by hydrolysis. If a trichloracetic acid filtrate of fresh muscle tissue is hydrolysed, a hydrolysis curve such as is shown in Fig. 8 (Curve 1) is obtained. In normal hydrochloric acid at 100° C. a certain fraction of the "organic" phosphate is hydrolysed to orthophosphate within seven minutes. If the acid hydrolysis is repeated with the filtrate of an autolysed minced muscle, a hydrolysis curve such as Curve 2 will be obtained. The rapidly splitting compound has disappeared whilst the orthophosphate starts at a correspondingly higher level. Now none of the hexose-phosphoric esters is liable to such rapid hydrolysis but pyrophosphate hydrolyses at just such a rate, and indeed pyrophosphate was successfully isolated in a pure state from fresh muscles.

It was found that all cells contained this pyrophosphate fraction but that the largest amounts are found in muscle and in yeast, which seems to indicate that the pyrophosphate may have some kind of share in the katabolism of carbohydrate. The pyrophosphate found in the muscle is not free but, as Dr. Lohmann's further investigations proved, is linked to adenylic acid. The latter is a derivative of nucleinic acid, and was discovered by Embden in muscles and proved by him and by Parnas to be the source of the ammonia which is set free in a muscle during activity. This adenylic-pyrophosphoric acid plays an unexpected rôle in the formation of lactic acid in muscle. Muscle and yeast cells contain the same co-enzyme, which takes the same share in alcoholic fermentation as in lactic acid formation. The lactic acid-forming enzyme in its purest form is able to produce lactic acid from added carbohydrate when phosphate and boiled muscle juice (co-enzyme solution) are added. If, however, the boiled muscle juice is made from a stale extract, it turns out to be unfit for the activation of the purified enzyme solutions. Its activity is restored if a certain fraction from the barium precipitate of a muscle extract is added. Adenyl-pyrophosphoric acid is the effective substance in the barium precipitate. During autolysis of muscle as well as during incubation of fresh muscle extract this nucleotide is decomposed, the pyrophosphate group being split off and ammonia lost, leaving inosinic acid (hypoxanthine-ribose-phosphoric acid). An autolysed co-enzyme solution becomes effective again by adding pure adenyl-pyrophosphoric acid which has been obtained from fresh muscle extract. We must, therefore, consider adenyl-pyrophosphoric acid as a member in the chain of substances necessary for lactic acid production or alcoholic fermentation, since the above experiments can be repeated with the same result by using well-washed dry yeast. The nucleotide compound becomes effective in the co-enzyme system only together with a second constituent; we may, therefore, consider it the complement of co-zymase. Now it was found that adenylic acid itself shows this complementary activity, and the explanation of this fact is very interesting. Lehnartz, in Embden's laboratory, described an increase in pyrophosphate in muscle-press juice when adenylic acid was added, and we then realised that adenyl-pyrophosphate was synthesised from adenylic acid in the presence of orthophosphate by means of enzyme extract of muscle. This peculiar synthesis goes on extremely fast for a couple of minutes after the adenylic acid has been added. Here we have an explanation of Euler's observation that pure co-enzyme preparations, if they were effective, always contained adenylic acid.

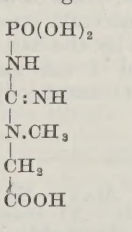
FIG. 9.



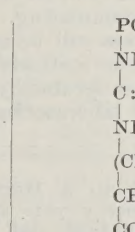
The titration curve of arginine-phosphoric acid before and after hydrolysis.

Creatine- and Arginine-phosphoric Acids.

Finally, I have to say something about the third phosphate fraction in muscle, the "phosphagen," which until 1927 was determined as part of the inorganic phosphate of the muscle. The Eggletons found phosphagen (creatine-phosphoric acid) in vertebrate muscles only; the muscles of invertebrates, which are almost entirely lacking in creatine, were naturally found to contain no creatine-phosphoric acid. The considerable importance of creatine-phosphoric acid being proved, we looked for its substitute in similarly acting muscles of invertebrates; this substitute we discovered to be arginine-phosphoric acid. Chemical investigation of both compounds revealed analogous structures.



Creatine-phosphoric acid.



Arginine-phosphoric acid.

That the guanidine group is bound directly to the phosphoric acid (i.e., that we are dealing with a

substituted amino-phosphoric acid) is shown by the similar behaviour of amino-phosphoric acid ($NH_2PO(OH)_2$) when submitted to acid hydrolysis. For the arginine compound this conclusion may also be drawn from the fact that the α-amino group remains free. Moreover, it follows from the electro-titration curves shown in Figs. 3 and 9. It will be seen that in both cases, when hydrolysis takes place in faintly acid solution (about pH 6), a free basic equivalent arises, because the strong guanidine group is liberated together with the very weak third valency of phosphoric acid. In spite of the great similarity of the two natural phosphagens, they show differences in chemical properties. For methodical reasons a most important distinction is that with creatine-phosphoric acid the splitting is strongly accelerated by molybdate, while it is just as strongly retarded in the case of the arginine-phosphoric acid. It is for this reason that arginine-phosphagen could not be detected by the method used to detect creatine-phosphagen.

The universal occurrence of the phosphagens is interesting from the biological point of view. All vertebrates, even amphioxus, contain creatine-phosphoric acid in their striated muscles. On the other hand, all classes of invertebrates utilise arginine-phosphoric acid. We have, therefore, evidence of a genuine chemical mutation at the beginning of the vertebrate stock. As to their physiological functions, the two substances are obviously equivalent. Arginine-phosphoric acid, however, is also contained in certain invertebrate unstriated muscles, but only in those which resemble the striated muscles of vertebrates, such as the longitudinal muscles of holothuria and the pharynx retractor of sipunculus, while it is absent, for instance, in the mantle muscles of the octopus. It is contained in the striated part of the muscle of pecten but not in the white, the so-called tonus, muscles. There it is obviously connected with the relatively rapid functions of the striated muscles. Indeed, it is decomposed with quite different degrees of facility according to the speed of response of the respective muscles; for instance, it is decomposed very fast in the rapid pecten muscles but only very slowly in the muscles of holothuria. Since the heat of hydrolysis of arginine-phosphoric acid is about the same as that of its creatine analogue, we may assume that it plays the same important rôle in the transformation of energy.

Although it is not possible here to give more than a limited section of the newly discovered facts concerning the acid-soluble organic phosphates in muscle, it is clear that much knowledge has been gained about them in the last few years. This knowledge is not sufficient yet to form a satisfying and coherent description of the chemistry of muscular activity, but we may confidently hope that in a few more years a working hypothesis will emerge and bring some degree of order into the mass of new facts which we are accumulating. I entertain great hopes that much progress will be made by the use of Prof. Hill's myothermic methods, and I am sure that progress will be accelerated by the pleasant coöperation between our two laboratories.

PRESENTATION TO A MEDICAL MAN.—Mr. Frank Barnes, who retired a year ago after 27 years' active service on the medical staff of Birmingham General Hospital, was recently presented with an illuminated address, and the hospital with his portrait. Mr. Barnes has been successively resident surgical officer, surgical casualty officer, assistant surgeon, honorary surgeon, and a member of the board.

THE TERCENTENARY OF QUININE.

RECEPTIONS AT THE WELLCOME HISTORICAL MEDICAL MUSEUM.

THE three-hundredth anniversary of the first recognised use of cinchona by Europeans has been celebrated during the past fortnight at the Wellcome Historical Medical Museum by receptions and the inauguration of a special exhibition. On Dec. 8th Cardinal Bourne took the chair, and an address was given by the Marquis de Merry del Val, Spanish Ambassador. The French Ambassador, Mr. A. J. de Fleuriau, and the Envoy-Extraordinary for Peru, Señor Don A. Gonzalez-Prada, also spoke. In the evening the Netherlands Minister, H. E. Konkheer R. de Marees van Swinderen, presided, Archbishop Goodier, S.J., gave the address, and General C. G. Dawes, American Ambassador, and Prof. F. van der Wielen, of Amsterdam, also spoke.

On Dec. 10th Mr. H. S. Wellcome, LL.D., took the chair, and Sir David Prain gave an address on the

History of Cinchona Bark.

The trees exploited in the forests of Loja, now Southern Ecuador, had been first examined critically, he said, by members of the French scientific expedition, under M. de la Condamine, which had spent the period 1737–43 in the measurement of the arc of a meridian in South America. The botanist of the expedition had been Joseph de Jussieu. As the result of his observations, Linnaeus, in 1742, had been enabled to found the genus cinchona in honour of the lady alleged to have brought the bark to Europe. It had been said that the natives who collected the bark had not known of its medicinal properties, but had believed it to be wanted for tanning leather or dyeing cloth. Natives, however, were not always anxious to convey their knowledge to their neighbours. The Marquis de Merry del Val had expressed the opinion—long held by the speaker—that the Indians had been well aware of the virtues of the bark, and de Jussieu had said that Jesuits in Peru knew its value in 1600. In this case the tercentenary was being celebrated a generation too late. By whatever means the bark had reached Europe, it had been known in Rome in 1639, having been sent to a Jesuit who had been sent there from Spain, and in 1643 had become a cardinal. The Jesuits had distributed the bark free to the needy and charged a high price for it to the wealthy. From Italy it had found its way to the Low Countries and thence to England, where a fortunate apothecary, one Talbor, had cured Charles II. with it. He had thereby incured the enmity of the London practitioners of his day and persuaded politically minded persons to assert that Charles must be a Catholic or he would never have taken a bark recommended by a cardinal. Indeed, the name of "Jesuit's bark" had long stood in the way of its use in medicine. Talbor had subsequently cured Louis XIV., who had bought the secret for £2000 and made it public. It had found favour with the courtiers; Lafontaine had written a long poem in honour of "quinquina," and in 1681 Mme. de Sévigné had written that it would soon become the fashion to take the bark after every meal like tea or chocolate. Racine, in a letter to Boileau, had said he did not know the honest man who, if he had taken quinine without effect, would have the hardihood to say so.

The cinchona bark recognised in the London Pharmacopœia of 1677 was the "Crown bark" of Loja; red bark appeared a century later. The

exploitation of the forest product had led to gradual diminution of supply and increased cost of collection. In 1735 Ulloa had called attention to the fate likely to befall the trade unless measures of forest conservation were taken. By 1785 the red bark (*Cinchona succiruba*) had been in general use in Europe and had been considered as useful as *C. officinalis*, and by 1790 yellow bark from Bolivia had become popular. In 1792, Fée had urged South America to cultivate cinchona, but instead exploitation in New Grenada had been undertaken. With the exhaustion of grey and yellow barks the exploitation of Columbian barks set in, and at last cultivation had been started: by France in Algeria in 1849, by Holland in Java in 1854, and by England in Ceylon and South India in 1861. Many climatic difficulties were, however, encountered; the climate of India was suitable but the soil was less satisfactory. Moreover, there was a difference in the adaptability of particular kinds of cinchona to changed conditions: Columbian barks had not flourished in Asia; red and grey bark had accommodated themselves, even to the unsuitable soil and climate of the Himalayas, and yellow bark grew in Sikkim and Burma but not in Ceylon and South India. The alkaloid content of different barks also varied, and the cultivator had to pay attention to the selection of strains, and still more of particular kinds. From the economic standpoint the nature of the alkaloids was even more important than their total amount.

Sir David Prain then proceeded to a discussion of the value of the various alkaloids. A vote of thanks to him was proposed by Mr. J. Ramsbottom, who mentioned the historical material now on show at the Linnean Society's rooms, and referred to the work of Sir Hans Sloane in popularising the bark. Prof. E. J. Salisbury, seconding, paid a warm tribute to the work of Dr. Wellcome and others for their synthesising influence in an age when specialisation was causing workers in different branches to become further and further divided. Sir Reginald Wingate gave some reminiscences of the Sudan, and the work of the Wellcome laboratories there.

Sir John Rose Bradford took the chair on the evening of Dec. 10th when an address was given by Sir Humphry Rolleston, who reviewed the history of quinine with many interesting and erudite anecdotes.

Therapeutics of Cinchona.

About 30 alkaloids had been obtained, he said, from cinchona bark, and they were all general protoplasmic poisons. The crystallisable ones were quinine, cinchonidine, quinidine, and cinchonine. The most powerful antiseptic was quinine, followed in order by quinidine, cinchonidine, and cinchonine. Quinidine was less effective in malaria than quinine, but was the most valuable in restoring the heart rhythm. Cinchona and its alkaloids had been used in a very wide variety of diseases. It had been given in fevers of all kinds, especially in the early days. Its vogue in the prevention of malaria was only second to its curative effects. Its reputed antipyretic action could not be explained by any influence on protein metabolism (Hardikar). On account of their action as general protoplasmic poisons, quinine and its derivatives had some action as local anæsthetics, acting on the nerve-ending. Bromides had largely superseded quinine in Ménière's disease because its local toxic action caused labyrinthine disorder. Small doses increased the activity of smooth muscle and had been thought to shorten labour and favour uterine retraction. The alkaloids were the only real specific for malaria, although hundreds of other drugs had been recommended. In 1791 A. E. Brande had declared that angostura bark was as good in ague, dysentery, and putrid sore throat. In 1792 Samuel James had published observations on the superiority of a species of willow in the cure of agues, intermittent fevers, fluor albus, abscesses, and hæmorrhages, while in 1803 G. Wilkinson had advised broad-leafed willow bark for various diseases. In 1793 William Roxburgh had compared a species of mahogany with the Peruvian bark. More recently, organic arsenical preparations had been shown to be useful adjuvants, but were not specifics. Thomas Fowler (1736–1801), of "Fowler's solution," had written to Andrew Duncan that on several occasions he had been cured of remittent fever by eight drops of the "mineral solution of arsenic" thrice daily. The statement that malarial parasites might become resistant to quinine was based partly on reports of cases, and partly on the analogy with trypanosomes and other protozoal parasites. In fact, however, quinine-resistant plasmodia were very rare. Cases where quinine seemed not to control the fever were probably accounted for by failure of absorption or inadequate dosage. How exactly it exerted its action was not yet clear; it might act indirectly by producing a metabolite in the tissues. Hatcher and Weiss had estimated that 95 per cent. of quinine injected intravenously disappeared from the blood in five minutes and thought that it collected in the capillaries. Another view was that quinine favoured the production of antibodies, and it had been thought to form a film on the corpuscles and so prevent the entrance of the parasites. Quinidine was the dextro-isomer of quinine; its real nature had been determined by Pasteur in 1853. It had, weight for weight, five times as powerful an action as any other alkaloid in restoring the normal heart beat in auricular fibrillation. Hydroquinidine, the chief impurity of commercial quinidine, had a slightly more powerful action. Ethyl-hydrocupreine had been advocated for pneumococcal infections, but had proved disappointing in man.

Mr. A. R. Melluish proposed a vote of thanks to Sir Humphry Rolleston, and pointed out the aid given by pharmacists and chemists to the use of quinine. He deprecated the fact that only 10 per cent. of the quinine produced to-day came from the British Empire. The vote was seconded by Lieut.-Colonel C. T. Samman, who pointed out that a former Master of the Apothecaries had invented field cases for the transport of the plant.

Malaria and Quinine.

At a reception on Dec. 15th Sir Charles MacWatt, Director-General, I.M.S., 1922–26, spoke on malaria and cinchona in India, admitting that he had himself taken a daily ration of quinine over a period of 25 years. No one who cannot take quinine should, he thought, be passed as fit to reside in malarious regions of the tropics. It was unfortunate that at present India supplied only 4 per cent. of the cinchona bark needed, and he asked for further and intensive efforts to increase the production of cinchona within the British Empire. On Dec. 17th Mr. T. E. Wallis, reader in pharmacognosy—a subject of study recently admitted into the degree examination of the University of London—described how the pharmacognosist is able to define the form of cinchona bark most serviceable to the physician, to control the purity and identity of the drug, to analyse materials containing it, and to suggest new directions in which the bark may possibly be still further utilised. At the final meeting on that evening, Dr. G. Carmichael Low,

as president of the Society of Tropical Medicine, occupied the chair, and Dr. P. Manson-Bahr gave an address on quinine therapy in malaria from the aspect of the practical physician. He was followed by Dr. H. H. Dale, director of the National Institute for Medical Research, who commented on the curious fact that the medicinal treatment of malaria had changed only in detail during the last 300 years, in striking contrast to that (say) of syphilis or kala-azar. The cinchona alkaloids were still without a serious rival in the treatment of malaria, but why these alkaloids in particular were antagonistic to malaria infection remained a mystery. It was, he said, the great merit of Ehrlich that he had focused the search for remedies acting on the causes of infection, not simply on its symptoms; the resounding success which he achieved in the case of salvarsan had led to a hope of establishing a general connexion between chemical structure and biological effect, which was not yet realised. We were still at best only groping towards it. Although nothing better than cinchona had yet been synthesised, the work of W. Roehl on the action of the synthetic plasmoquine opened up a new field of investigation. Dr. C. M. Wenyon, director-in-chief of the Wellcome Bureau, gave some striking illustrations of the prompt action of quinine on the malarial parasite, although, he said, cinchona is powerless to prevent malarial infection. He was one of those who doubted the value of the daily prophylactic dose, if continued for longer than a month or two; but he looked forward to the day when there would be no more malaria and people would refuse any longer to tolerate the mosquito. The evening ended with a warm tribute to the organising ability and generosity of Dr. Wellcome, to which he briefly responded.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

SCHOOL CONDITIONS.

THE national executive of the Irish Trade Union Congress has requested the Minister for Education in the Irish Free State to receive a deputation to discuss the condition of the primary school buildings in the rural areas, and the need for providing funds for repairs and upkeep. At present the schools are the property of the managers, usually the local clergymen, and the State has no responsibility for their condition or their upkeep. The national executive is of opinion that many of the country schools are a menace to public health. A medical inspector in County Cork is quoted as saying that if a certain school remained open he would not be responsible for the health of the district. The Minister for Education has admitted that 111 schools require the provision of sanitary accommodation. This probably means that they are without any such accommodation, for, in the great majority of country schools, the only accommodation provided is an inadequate privy, which is seldom cleaned. The executive quotes examples of school buildings in a shockingly insanitary condition in several counties. One school in County Kerry, which has an average attendance of 112 children, is situated in the middle of a village, and has no sanitary accommodation whatever. The school medical officer for County Cork has reported that in 56 per cent. of the schools inspected by him the accommodation is unsatisfactory.

The Labour executive is calling attention to an age-long scandal on which the medical profession has time after time attempted to rouse the conscience of the Government. The head of the primary educational system under the old régime told a deputation which interviewed him on the subject years ago that he was not concerned with the health of the children attending the public schools, that his only business was with their education. When the Act providing for medical inspection of school-children became law in 1919, no power was given to the medical inspectors to inspect or report on the condition of the school buildings. The Government feared the effective opposition of the school managers if such a clause were inserted in the Bill, and the duty of the inspectors as laid down by the Act and the Regulations was confined to attention to the children themselves. Fortunately no such limitation affects the functions of the county medical officer of health, whose duty it is to report on any conditions adversely affecting the health of the people of his county. The Labour executive is of opinion that, until the burden of the care of the school buildings is taken from the shoulders of the managers and put on the public, the buildings will remain a menace to the health of the children.

In the meantime it is pleasant to note a small advance in the care of school-children which was made by the Dáil just before its adjournment last week. Hitherto the power to provide meals for school-children was limited to the authorities of the four county boroughs. A private Bill, introduced by Mr. Shaw, which proposed to grant similar powers to other urban authorities, was before the Dáil. It had little chance of passing through its several stages before the recess, but the Minister for Local Government and Public Health came to its rescue and adopted it as a Government measure, thereby speedily passing it through its remaining stages. The leader of the Labour Party, Mr. O'Connell, urged that similar powers should be given in rural areas as well as in urban, as was indeed recommended four years ago by the Committees of Inquiry on National Health Insurance and the Medical Services. The need for school meals is greatest in the rural areas where many of the children have travelled long distances. Dr. O'Higgins properly reminded the House that the argument for school meals is not based on the poverty of the children but on their requiring a warm meal in the middle of the day.

APPEALS BY VOLUNTARY HOSPITALS.

MOST voluntary hospitals throughout the country find themselves at the end of any year with a debit balance on routine maintenance expenditure. When extensions, reconstructions, or renewals on a large scale are contemplated, special appeals have to be issued. The present time of industrial depression was deemed inopportune for the launching of some of the appeals which had been contemplated this year; other hospitals had already embarked on schemes for capital expenditure which were deemed to be essential, and decided that it was necessary to try to raise extra money.

We append a list, which is by no means complete, of hospitals with outstanding special appeals. The information it contains was received at various times during the autumn months, and some at least of the hospitals concerned have since collected more money.

If notice is received within the next few days of other hospitals which are appealing for help for special purposes, a further list will be published.

TABULATED LIST OF HOSPITALS WITH SPECIAL APPEALS.

Name of town and hospital.	Date of appeal.	Amount required.	Amount received.	Purpose.
		£	£	
ALTON: Lord Mayor Treloar Cripples' Hospital	1929	100,000	50,000	To rebuild institution at Alton.
ARUNDEL and District Cottage Hospital	1930	8,000	6,300	Erection of a new cottage hospital.
BATH: Royal United Hospital ..	1929	100,000	62,000	Building of new hospital.
BEXHILL Hospital	1930	13,000	1,500	Building and equipment.
DONCASTER: Royal Infirmary and Dispensary	1925	156,000	110,000	Hospital and nurses' home.
EDINBURGH: Royal Infirmary ..	1930	500,000	154,000	New maternity and gynæcological wards with antenatal and out-patient departments.
EXMOUTH Hospital	1930	6,000	1,000	New children's and private wards; out-patient department; and X ray equipment.
GLASGOW: Victoria Infirmary ..	1930	105,000	61,377	Building and equipping auxiliary infirmary.
GLOUCESTER: Gloucestershire Royal Infirmary and Eye Institution	1929	20,000	12,500	Extension of wards and private beds, and out-patient department.
GOSPORT War Memorial Hospital	1930	15,000	9,400	Extension of administrative block and out-patient department, and increase of beds.
ILFORD: King George Hospital..	1928	200,000	100,000	Conversion of emergency to general hospital, and extended accommodation.
INVERNESS: Northern Infirmary..	1925	Increased to 140,000	120,000	Reconstruction and extension.
LONDON:				
Cancer Hospital (Free) ..	1928	150,000	22,000	Accommodation for paying patients and out-patients, and new radiological block.
City of London Hospital for Diseases of the Heart and Lungs..	1928	26,000	14,000	Surgical and X ray blocks, sanitary improvements.
East London Hospital for Children	1925	30,000	5,000	Building a nurses' home.
Great Ormond-street Hospital for Sick Children	1930	Not announced.	42,000	Rebuilding hospital on present site and on land adjoining.
Hospital for Tropical Diseases	1929	35,000	12,500	Construction work and endowment fund.
Middlesex Hospital	1925	1,220,000	974,000	Reconstruction.
Queen Charlotte's Maternity Hospital	1927	Over 500,000	150,000	Wards for puerperal fever and maternity cases.
Queen Mary's Hospital for the East End	1930	35,000	Over 1,000	To pay off deficit on maintenance and building fund.
Royal Free Hospital	1928	600,000	425,000	Extension of V.D., pathological, obstetrical, and gynæcological departments; provision of private wards; and completion of nurses' home.
Royal London Ophthalmic Hospital	1930	24,000	4,000	Extension of out-patient department and laboratories, and new theatre.
St. Bartholomew's Hospital..	1929	1,000,000	Not announced.	Surgical blocks and theatres; reconstruction of out-patients' department; maternity, gynæcological, and children's wards; research.
St. Mary's Hospital	1930	250,000	20,000	Paying wards; rebuilding medical school and nurses' home; extension of maternity wards.
St. Peter's Hospital for Stone	1928	24,000	13,000	Private beds; new out-patient department; reconstruction; and new pathological department.
Western Ophthalmic Hospital	1925	40,000	30,000	Rebuilding.
LOUGHBOROUGH and District Hospital	1928	40,000	33,400	New theatre; additional beds and maternity ward; reconstruction.
MANCHESTER: Ancoats Hospital..	1928	100,000	36,000	Additional beds, theatres, and special services.
MANCHESTER Northern Hospital for Women and Children ..	1926	150,000	90,000	New general hospital.
MARGATE and District General Hospital	1926	70,000	60,000	New general hospital.
SOUTHEND and District New General Hospital	1926	145,000	115,000	To build new hospital.
WEMBLEY Hospital	1930	10,000	1,016	Hospital extension.
WORKSOP: Victoria Hospital ..	1930	12,000	4,800	Hospital extension.

PANEL AND CONTRACT PRACTICE

The New Essex Medical Service.

THE Essex Public Medical Service was started in 1924 to provide medical attendance on the families of insured persons on a contract basis. The last annual report shows that there were 16,750 subscribers and 127 doctors working it, the average payment per subscriber being 10*s*. 1*d*. Last June a proposal was made to extend the service so as to include patients whose incomes lie between £250 and £400, and the central committee have agreed in principle to the formation of the new service, using the existing office and staff for its administration. But the new service will not be controlled by the E.P.M.S.; it will be responsible for its own finances and administration. The chairman will be nominated, however, by the parent committee, the remaining members of the new committee being three doctors who are actually working the new service. The conditions now set forth are intended to serve for the first year or two, when experience may make it feasible to draw up more detailed rules and regulations.

The rate of payment is 30*s*. per annum for each member of the family, adult or child. If there are more than two children under 16 years of age in a family, the first two will pay 30*s*. each and the others 20*s*. each.

Thus a family of four (parents and two children) will pay £6 per annum—30*s*. per quarter—in advance. If no adult member of the family is on the book, the reduced rate for children above two in number will not apply. In the case of an exceptionally large family, the doctor may arrange with the office for special rates for children. Subscribers will have the option of paying direct to the office or to a collector of the E.P.M.S., who will call on agreed dates. A subscriber is entitled to benefit three weeks after acceptance by a doctor.

Administrative expenses are to be met as follows. A charge of 6*d*. per quarter is to be paid on each subscription book towards expenses of administration. The service will pay the E.P.M.S. £20 per annum for the use of the office (one-fourth of the expenses of rent, heating, lighting, cleaning, and telephone). It is estimated that at the end of about a year, after the first 500 families have joined the service, the cost of administration will be met by a deduction of 5 per cent. from the total collections. For the present it is proposed to deduct 20 per cent. from collections, which will be reduced to 15, 10, and 5 per cent. as the office income balances expenditure. Doctors who join the service after the 20 per cent. deduction has been reduced may be required to pay an entrance fee.

A subscriber to the service is entitled to receive from his medical attendant:

(*a*) Medical and surgical treatment within the competence and skill of a general practitioner at the surgery of his medical attendant.
(*b*) When his condition requires it, ordinary medical and surgical treatment at his place of dwelling.
(*c*) All needful medicines.

He is not entitled, in consideration of his ordinary subscription, to medical service in respect of:

(*a*) Confinements and miscarriages, or to illnesses arising therefrom within ten days.
(*b*) Vaccinations.
(*c*) Administration of a general anæsthetic.
(*d*) Certificates and reports.
(*e*) Such expensive drugs or preparations as may from time to time be determined by the Committee.
(*f*) Examinations, court attendances, &c., under common law, and workmen's compensation, employers' liability and other statutes.

The class of patient to be included is one specially hard hit by taxation, high cost of living, and the heavy expense of education; moreover, as trade gets worse, salaries are going down. It is the class which, in the majority of cases, is responsible for doctors' doubtful and bad debts. It is believed that the service will prove of considerable financial benefit to doctors. It will bring in the breadwinner of the family (who is ineligible for the panel) and the family will be regular patients, in good seasons as well as in bad. There will be no bad debts and no trouble of keeping and collecting accounts.

The advantages and conditions of the service, so far as they concern subscribers, will be made known to such patients as the doctor may wish to invite to join it by means of a printed circular letter, which includes a form to be filled in by the patient and sent to his doctor. Copies of this circular letter will be supplied to doctors for sending to their patients, or, if preferred, will be posted direct to patients from the office.

The office of the new Essex Medical Service is that of the E.P.M.S. at 108, City-road, London, E.C. 1. Secretary: Mr. H. E. Norton.

Recurring Difficulties of Panel Practice.

At a recent meeting of the Paddington Medical Society Dr. E. W. Selby, a divisional medical officer of the Ministry of Health, spoke of some of the difficulties of insurance practice. He reminded his hearers that the regional officers of the Ministry were doctors who had had themselves much experience of insurance practice, and should be regarded as sympathetic colleagues rather than as inspectors. Their routine visits to panel doctors were found to be of great value for exchanging opinions and clearing up difficulties. Friendly investigation of prescribing on these lines had reduced from 20 to 2 per cent. the number of cases in which doctors had to appear before their panel committee. Speaking of the forms of medical record, Dr. Selby suggested that entries were most easily made at the time the patient was seen; if this were always done it would be easy for the doctor to make out an adequate report when a case was referred to the regional officer, when it was most important for the report to be sent promptly, especially if the patient were ill in bed. The reports made by the regional officers were, he said, advisory in nature; they always tried to take into consideration any extenuating circumstances connected with the patient's disability. He went on to deal with certification in short illnesses and in post-operative debility, where there was a tendency for disability to be certified for an unduly lengthy period, and admitted the difficulties of cases with permanent partial disability. Discussion showed that many practitioners found the certification of cases of pregnancy and post-partum debility to present difficulties; some of these might be overcome by the exercise of tact, but others could be met only by alteration of the certification regulations. A number of members pointed out that patients attending hospital were apt to remain "unfit" longer than was actually necessary; this was due in some cases to the doctor not receiving a report on the patient from the hospital, and to the fact that the hospital

did not sufficiently appreciate the necessity of getting the patient back to work. Prolongation of "unfitness" was sometimes due to the patient not being able to resume work in his particular employment except on a certain day of the week. There was also the difficulty of the patient who, owing to age or permanent partial disability, had to find some other and easier occupation.

Medical Benefit in Northern Ireland.

Our Belfast correspondent tells us that the first meeting of the Medical Benefit Council for Northern Ireland has been held. The chairman, Prof. R. J. Johnstone, pointed out that although as far as the administration of medical benefit was concerned the duties of the Council were in the main advisory, yet in addition the Council had the important duty of acting as a court of appeal in specific cases concerning the services rendered by individual doctors and chemists. The Minister of Labour said that the medical benefit scheme was one for the alleviation of suffering and for the preservation of life. His ideal of the medical service to be given by doctors to their insured patients was the same care, skill, and treatment as was given to ordinary private patients. He stressed the point that insured patients were private patients, for all had the free choice of doctor, the only difference being that the insured patient contributed weekly towards the remuneration of the doctor. The chairman said that all were agreed that the Minister's high ideal of medical service would be the aim of the medical men on the panel in Northern Ireland.

PUBLIC HEALTH SERVICES

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1929 statistics of three counties :—

Name of county and estimated (R.-G.) mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant mortality.	Young child (1–5 yr.) mortality.	Maternal mortality from childbirth.
Kent .. .. (1,145,300)	15·3	12·7	0·82	1·54	2·3	2·5	61	29	3·5
Durham .. (940,900)	20·2	12·9	1·06	1·09	3·0	1·5	94	57	6·2
Staffordshire. (709,900)	18·4	12·8	0·83	1·27	3·1	2·0	79	—	4·5

Registered stillbirths per 100 live births: Kent 3·4, Durham —, Staffordshire 4·2.

Kent.

Dr. A. Greenwood reports that the number of deaths showed an increase of 1666 on the total of the previous year. Diphtheria was less prevalent. There were 1941 cases with 148 deaths—a high case-fatality of 7·6 per cent. From many of the districts came reports of failure to secure the early use of antitoxin. An outbreak of true typhoid occurred in Northfleet U.D. in November–December. There were 17 cases with 7 deaths. Investigation tended to implicate meats sold in a cooked condition, but bacteriological examinations were negative as regards the handlers of foods in the shops. At the end of the year the tuberculosis waiting-list was: 32 for sanatoriums, 78 for hospitals, and 36 for surgical institutions. The number of patients at Lenham Sanatorium receiving artificial pneumothorax treatment increases. The out-patients attending for refills also increase, and extra accommodation has had to be made. About 24 per cent. of the syphilitic patients and 13 per cent. of the gonorrhœa patients cease attendance at the clinics before completing treatment. These percentages are similar to those obtained in previous years.

The county scheme for crippled children continued to operate satisfactorily. The base hospital at Swanley for "long-stay" cases has 48 beds for tuberculous and 32 for other crippling ailments of Kent children. Hospitals at Maidstone, Canterbury, and Dartford provide for "short-stay" cases, and there are eight out-patient clinics at which massage, remedial exercises, and other forms of physiotherapy are carried out in a systematic manner, and at which instructions are given as to the carrying out of physical exercises daily at home. Many of these out-patients are supplied with surgical appliances which need repair and adjustment. Twelve outside complaints of tuberculous milk were received and as a result seven cows with tubercle of the udder were found and slaughtered, and one suffering from tuberculosis but with the udder unaffected was also slaughtered. Four of the district medical officers have arranged to send milk samples to the county laboratory to be examined for tubercle. The medical officers of districts also report condemned tuberculous carcasses in order that the herd of the farm from which they came may be inspected. An outbreak of food poisoning occurred at a social with 117 persons present. Within three-quarters of an hour of the serving of refreshments about 30 persons were taken ill. The cause appeared to be antimony in the enamel of the jugs in which the lemonade had been made.

The arrangements for hop-pickers' camps seem to improve every year. About 60,000 pickers come from London for a month, and the growers provide for these, but there may be an equal number of relatives and visitors especially at week-ends. Hence overcrowding! Improved portable latrines are gradually replacing the objectionable fixed type. It is difficult to provide cookhouses with safe fires at a reasonable cost, and many cases of burns and scalds are caused by the open gypsy fires. An improved arrangement for water-supply last year was the installation, in some cases, of cisterns with a number of spring anti-waste taps. These not only save wastage but abolish the evening queues of water drawers.

Some improvement in the housing situation is perhaps indicated by an increase in the numbers of houses found unfit for human habitation, of closing orders made, and of houses where defects were remedied. New houses also showed an increase. Nevertheless, Dr. Greenwood points out that nearly 6000 houses are required *now*. In September representatives of the Home Counties held a conference with respect to the deposit of London refuse. A resolution was passed that no local authority should be permitted to deposit refuse within the area of another authority without the approval of that authority and of its county council, with a right of appeal to the Minister of Health. Dr. Greenwood shows that there is a comic side to this question of refuse dumping. Last year Folkestone complained because Cheriton tipped its refuse within the borough, whilst Cheriton complained of a Folkestone dump of refuse within its boundaries.

Durham.

Dr. C. Franks presents the report as the information required was not available when his predecessor

Sir T. Eustace Hill retired. As the result of the influenza epidemic the death-rate in the first quarter was 16·5 and the infant mortality 120. There was much less small-pox. The notifications for 1927, 1928, and 1929 were: 5101, 1124, and 473, whilst the deaths were 19, 3, and 1 respectively. Although there was an increase in the number of new houses erected both by local authorities and by private enterprise, no appreciable difference has been made in the grave conditions of overcrowding, and many new houses are required to replace those unfit for human habitation. A new fixed minimum income scheme has been adopted for the blind. The number of blind persons on the register shows an increase of 279 to 1321, as the result of more accurate ascertainment. Under the new scheme an augmentation grant up to 20s. per week is made to every unemployable blind adult on the register. From April 15th to the end of the year the cost was £9470. On Dec. 21st, 1929, there were 275 urgent cases of mental defect awaiting institutional treatment. Plans for a colony for 1000 mental defectives at School Aycliffe near Darlington are under consideration. The new veterinary section is now in operation. The chief veterinary officer began work on April 1st and four assistants on Oct. 1st. Animals slaughtered under the Order were 237, of which 93 had tubercle of the udder, 3 were giving tuberculous milk, 42 had tuberculous emaciation, 97 had other tuberculous lesions, and 2 were not affected. Of 316 samples of milk taken by the Food and Drugs Acts inspectors 6·6 per cent. were found to be tuberculous.

There was a large reduction in the prevalence of diphtheria but the case-fatality increased from 5·2 to 5·5 per cent. The deaths from measles, 218, were higher than in any year since 1925 when the total reached 450. There were 131 notifications of ophthalmia neonatorum and in 13 cases permanent damage of one or both eyes occurred. It is believed that earlier hospital treatment would have prevented this permanent damage. The county council has purchased a house at Bishop Auckland for a combined centre for all their medical services, and the antenatal clinic of the County Maternity Home has been transferred to it. Special sessions are held at many centres for the expectant mothers, and at some centres the appointment system has been successfully adopted. Grants from the Coal Fields Distress Fund have been instrumental in sending mothers and babies to convalescent homes or to the seaside, and also in providing clothing and boots and extra nourishment for necessitous families. The families receiving extra nourishment from this fund at the end of the year numbered 1779.

The thorough biological and chemical survey of the River Tees is still in progress and likely to prove a source of valuable information for all river custodians. It is considered that of the three rivers of the county, the Tyne and the Tees, each belonging as they do to two counties, would be better looked after by Rivers Boards.

Staffordshire.

Dr. W. D. Carruthers gives the usual table with respect to the hydrographical survey of the River Trent. The analyses made in July and September show how the Trent is affected by the junction with its various tributaries in the county. A percentage of oxygen saturation below 65 means that the water cannot support fish life. The first analyses taken after the river leaves "the Potteries" are far below this figure of 65. The first improvement comes after the Sow flows in from the Stafford region, when the figures for oxygen saturation are 49·5 and 56·5. Self-purification then goes on, but receives a bad set-back from the junction with the Tame, and finally, as the river joins the Dove, on the border of the county, its water for the first time reaches the "fish life" standard with figures of 76 and 62 respectively for July and September. The new houses built were 3479 compared with 2488 for the previous year, but at the end of the year there were fewer houses in course of erection. There is still much overcrowding, and it is not possible to construct houses at an economic rent for a large section of the population.

Sixty-one outside complaints of tuberculous milk were received, and as a result 38 animals were slaughtered under the Order and 7 disposed of by the owners for slaughter. On the other hand, eight complaints of tuberculous milk were made to outside authorities and in six instances the investigations conducted had a negative result. Returns are given of the milk-sampling for the last 10 months of the year. Of 1238 ordinary milk samples 74, or 6 per cent., were tuberculous. Of 90 Grade A (T.T.) samples one was tuberculous, whilst of 561 Grade A samples 14 or 2·5 per cent. were tuberculous.

There were 40 notified cases of dysentery; 33 occurred in Cheadle R.D., of which 31 were patients at the Mental Hospital, and of these four died. The Joint Committee for Tuberculosis obtained a magistrate's order under Section 62 of the Public Health Act, 1925, for the compulsory removal of an advanced consumptive to a poor-law institution. The man in question had left hospital against medical advice and his habits made it essential that he should not remain at home. The order was made for a period of three months and renewed for a like period, during which the patient died.

The total births numbered 13,125. Of these, midwives attended 10,154 and sent for medical aid in 3154 (31 per cent.). The midwives also attended 1551 cases as maternity nurses. The number of births which were not attended by midwives was therefore 1420; the largest percentage of such births being in the northern sparsely-populated area of the county. Facilities are to be provided at every centre for antenatal and postnatal work, but it will be a considerable time, says Dr. Carruthers, before they are extensively used by the mothers.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED DEC. 13TH, 1930.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 137 (last week 95); scarlet fever, 2029; diphtheria, 1468; enteric fever, 26; pneumonia, 997; puerperal fever, 53; puerperal pyrexia, 111; cerebro-spinal fever, 11; acute poliomyelitis, 8; acute polio-encephalitis, 3; encephalitis lethargica, 11; continued fever, 1; dysentery, 14; ophthalmia neonatorum, 84. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Dec. 16th–17th was as follows: Small-pox, 189 under treatment, 5 under observation (last week 206 and 5 respectively); scarlet fever, 1869; diphtheria, 2122; enteric fever, 12; measles, 87; whooping-cough, 115; puerperal fever, 25 (plus 11 babies); encephalitis lethargica, 121; poliomyelitis, 1; "other diseases," 51. At St. Margaret's Hospital there were 16 babies (plus 7 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 57 (0) from measles, 6 (0) from scarlet fever, 18 (2) from whooping-cough, 35 (3) from diphtheria, 49 (12) from diarrhœa and enteritis under two years, and 60 (9) from influenza. The figures in parentheses are those for London itself.

The fatal case of enteric fever was reported from Birmingham. Fifteen deaths from measles occurred at Hull, 11 at Liverpool, 4 each at Bristol and Swansea. Five deaths from diphtheria were reported from Birmingham and from Liverpool, 4 from Manchester, and 3 from Willesden. Diarrhœa accounted for 6 deaths at Birmingham, 3 each at Liverpool, Manchester, and Sunderland.

The number of stillbirths notified during the week was 286 (corresponding to a rate of 46 per 1000 births), including 51 in London.

DEATH *with* SMALL-POX.

A FATAL case provisionally assigned to small-pox in the return for the week ended Dec. 6th was that of an unvaccinated boy of 5. Dr. E. W. Caryl Thomas, medical officer of health for Dagenham U.D.C., tells us that as the result of two cases of small-pox occurring at the school the absentees were visited. Amongst these were the family D, which consisted of four members, Mr. D., Mrs. D., L. D., aged 7, and E. D., aged 5. Apart from Mr. D., who was vaccinated in the army, none of the family had been vaccinated. At the time of Dr. Thomas's visit on Nov. 27th, the elder boy, L. D., exhibited scars suggesting a recent attack of small-pox. E. D. had a number of scars and some scabs; the onset of his eruption was some four weeks previous. In addition, the mother was suffering, her onset being Nov. 9th. Just before the visit the family doctor had been called in to the boy E. D., who was complaining of sore-throat, and he notified him as suffering from diphtheria. As there were some scabs still on his body, he was removed to the L.C.C. small-pox hospital as a double infection, in preference to the local isolation hospital. The boy died some days after admission, the cause of death being certified as diphtheria.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS.

UNEMPLOYED PERSONS AND HEALTH INSURANCE.

PROLONGATION PROPOSAL.

Mr. GREENWOOD (Minister of Health) in moving the second reading of the National Health Insurance (Prolongation of Insurance) Bill in the House of Commons on Dec. 17th, said that during the first period of unemployment after the war the Coalition Government decided that as the number of unemployed stood at 1,250,000 they would not permit people to suffer from the effects of prolonged unemployment, and they increased the benefits of the National Health Insurance Act. In 1921 the first Prolongation of Insurance Bill was passed and it was continued until 1928 when it was brought to an end. The question had now been reconsidered and in view of the fact that so many people were unemployed and would be excluded from benefit, he had now taken advantage of the powers given under the Act of 1928 to prolong by regulation the period of insurance for these people for a further year. Those powers, however, were now exhausted, and if the position was to be dealt with it could only be by fresh legislation. The situation to-day was even more urgent than it was in 1921. To-day, with old-age pensions, widows' pensions, orphans' allowances, as well as health insurance, it was infinitely more serious if a man's insurance rights were exhausted. Recent experience had shown that the persons who most needed benefit were those who had suffered longest from unemployment and were, in consequence, somewhat enfeebled by malnutrition. Therefore it had been decided to continue these people in their insurance rights.

A SUGGESTED DEPARTURE FROM PRINCIPLE.

It had been suggested, said Mr. Greenwood, that there might be in this Bill the beginning of some serious departure from insurance principle, that it was the start down the slippery slope which would end with the Health Insurance Fund being in deficit, and that a situation similar to that in regard to unemployment would arise. That was the wildest possible exaggeration. The Government were really maintaining the insurance principle. The only point was that instead of the person paying his contribution for himself the Government were going to pay it for him. The approved societies could not be asked to bear this burden. It was impossible to say exactly how many people were affected by the Bill; they were persons who had not done any work for two and a half years or more. The number would probably be about 80,000. The cost would be between £80,000 and £130,000, say roughly £100,000. In addition, it was proposed to pay the State contributions as would have been the case if those persons were paying their own contributions, and that would cost between £14,000 and £24,000.

THE PRINCIPLE DISCUSSED.

Sir KINGSLEY WOOD said that this question had been interesting the approved societies for many months, and they had pressed the Minister of Health on it. The scheme did not affect a very large number of people. There was no proposal in the Bill to continue full insurance benefits; most of the benefits would be at only half rate. The maximum cash amount an insured man could get was 7*s.* 6*d.* per week, and in the case of a woman 6*s.* They might receive very much less, something like 3*s.* 9*d.* per week in each case. The principle hitherto followed by friendly societies and approved societies was that when an insured person was unfortunately not able to keep up his contributions his benefits must cease. That principle was being departed from in this Bill, and he asked whether it was the intention to pursue the same path in regard to health insurance as they had already pursued in regard to unemployment insurance. If they once admitted the principle that the State should pay the contributions of certain people who had fallen out of insurance benefit then there were other classes of insured people who would ask that their claims should also be considered.

THE BILL ACCEPTED.

After further debate,

Mr. GREENWOOD assured the House that before another year the Government would be in a position to make definite constructive suggestions for dealing with this problem.

Sir KINGSLEY WOOD said that in view of Mr. Greenwood's undertaking that there should be further inquiry into this matter, the opposition would not offer any objection to the remaining stages of the Bill.

The Bill was read a second time and passed through all its remaining stages.

In the House of Lords on Dec. 18th the National Health Insurance (Prolongation of Insurance) Bill passed through all its stages.

VIVISECTION EXPERIMENTS.

Lieut.-Commander KENWORTHY, in the House of Commons on Dec. 16th, asked leave to bring in a Bill to prevent the application of public money to vivisection experiments. He said that the British Medical Association had been good enough to send him, and he dared say to every other Member of the House, a document in reference to the Bill asking for it to be opposed, and the ordinary reading of that document would make it appear that he (Commander Kenworthy) wished to prevent those vivisection experiments. He might wish to do so, but it was not intended to prevent them by this Bill. There was a very wide objection to the taxpayers' and ratepayers' money to the extent of £130,000 or £145,000 a year being devoted to subsidising these experiments. If they were to go on there were many wealthy institutions which could continue to support them. There had been a tremendous increase in the number of these experiments and he did not think that that increase could possibly be warranted by the results. In 1927 there took place 13,871 cutting operations with anæsthetics, and 279,431 experiments

without anæsthetics—a total in 1927 of 293,302. In 1928 the figure had risen to 315,891, and in 1929 to 403,142—an increase of 87,250 in 12 months. That was unjustified and led to a great deal of unnecessary expenditure. In 1929 there were 513 animals, including cast Army horses, exterminated by poison gas experiments, all paid for by the taxpayers' money against the conscience and desire of a large majority of people in the country. This Bill was introduced in 1922 and 1924 and he was supported then by the present Secretary of State for Scotland, the present Home Secretary, the present Foreign Secretary, the present Secretary of State for War, and the present Secretary for the Dominions. The Bill consisted of only three clauses and was backed by Members of all three parties.

OPPOSITION TO THE BILL.

Major CHURCH, in opposing the Bill, said that very few Members of the House would be reluctant to have a full discussion on this very interesting and important subject if there was time for it. But since that was not possible in the circumstances he must, on behalf of the Medical Research Council, on which body he had the honour to represent that House, oppose the Bill, not because he believed in giving unnecessary pain to animals. There were very few in that House who would like to see the slightest harm done to any of the smaller creatures. There were very few who would view with anything but a feeling of misgiving any experiment clumsily carried out on any animal, whether for the purpose of curing it of a disease, or in the course of experiment on the animal with the object of saving human life. A great deal of sentiment was naturally brought to bear on a subject of this kind; but they had not merely to consider sentiment, they had to take into account the advance of knowledge and the uses to which animal experiments were put for the purpose not merely of saving human life, but also of saving the lives of animals. He would remind Lieut.-Commander Kenworthy that it would be extremely difficult to differentiate between money spent directly by the State in State research institutions, such as the National Institute for Medical Research at Hampstead, and similar places, and that which was granted for universities and other research bodies in the country carrying out experiments on animals. He also pleaded with the House to use some common-sense with regard to the figures which had been quoted by his hon. and gallant friend. They should realise that the greater number of those experiments were experiments in which there was not the slightest suspicion of pain being inflicted on the animals, in which there was neither anæsthetic used or necessary. A large number of those experiments were carried out on mice, rats, guinea-pigs, and animals of that kind for the purpose of testing the various diets which were afterwards standardised for the cure of certain specific diseases among children—rickets for example. A cure for rickets was established by experiments on animals. Every one of such experiments had to be tabled as experiments and had to be done under licence from the Home Secretary. Under the Bill these feeding experiments would be excluded. Many friends of his at the present time were engaged in a whole series of experiments on mice and rats, hedge-hogs, and other similar animals for the purpose of carrying out certain tests with regard to pituitary and other glandular extracts. Those experiments were of the simplest possible kind, and consisted of the injection by hypodermic syringe at certain times of certain substances. Experiments of that nature were well within the ambit of this Bill. He reminded the House that experiments of a serious nature were only allowed under regulations and only under the most stringent conditions were animals allowed to live after serious experiments had been carried out on them. In all other cases the animals were destroyed. The experiments were carried out under an anæsthetic.

LEAVE REFUSED.

On a division, leave to bring in the Bill was refused by 170 votes to 156—majority against, 14.

TREATMENT OF VAGRANTS.

In the House of Lords on Dec. 10th the Bishop of EXETER asked the Government what steps had been taken to secure more uniform and humane treatment of vagrants, and especially whether any steps had been taken to found any institutions to train juvenile vagrants; also whether public assistance committees had any power to make grants towards the maintenance of existing institutions for the reclamation and training of young vagrants; and moved for Papers. He said that they were very grateful for the Vagrancy Report, which had been rightly called the Casuals' Charter. He was, however, somewhat alarmed lest that report might remain only an aspiration and not come to be a reality. He was anxious that if any forward step was taken they should be certain that similar steps would be taken in every part of the country. They were very grateful for Dr. Lewis's report. It was the first time that they had really reliable data as to who the tramps were. Hitherto the popular idea had been that tramps consisted of people who would not work, and people who wanted work and could not find it. Those who had worked among them knew that there was a very large section who should rather be included under the term "cannot work." Dr. Lewis brought that fact out. The figures were very remarkable. He asserted with all his knowledge that a quarter of the tramps in the country were what were usually termed "mentals." Some were insane, a very large section were feeble-minded, and a good number had psychoneurosis. It altered the whole picture when one remembered that these poor feeble-minded creatures were being allowed to wander about the country to look for work which did not exist, and which, if they found it, they could not do. Surely no one could commend a system which had that for its result.

THE CASUAL WARD.

The criticism he would offer was the assumption that the casual ward was to continue, for those who were employable would find it less helpful to get employment than it used to be. He agreed that that section was a small one. Dr. Lewis suggested that 80 per cent. were habitually users of the casual ward. Probably that 80 per cent. were more or less unemployable, but the 20 per cent. who were employable would find that the regulations advised in the report would make it harder for them to find work. In the first place, the casual wards were to be 15 miles apart. How could a man after tramping 15 miles look for work? There was a section who could be reclaimed—namely, those who were in the casual wards through drink. Dr. Lewis put the proportion as one in eight. They could not save these men merely by giving them short terms of imprisonment. He would like to see an alteration made in the law enabling men voluntarily to enlist in homes which it was hoped the counties would set up, and that voluntary enlistment should be binding on them for a definite time. Dr. Lewis pointed out that the intellect of these feeble-minded tramps was that of an ordinary boy of seven or eight years. Could they trust children of seven or eight to act sensibly without some discipline? These homes should not be regarded as prisons; he would much rather they were looked upon as hospitals or schools. Many of those who were feeble-minded could become quite useful citizens if they were properly trained, but there must be power to train them. He had visited one of these detention colonies in Switzerland, which had much impressed him. The men in it were there by sentence of a court.

The Bishop of ST. EDMUNDSBURY AND IPSWICH said the problem of dealing with vagrants was a

very difficult one. He believed that those tramps whose mental capacity was not up to a fair average formed quite a small proportion of the number of vagrants, and unemployment had very little to do with the question. If they made inquiry they would find that the number of vagrants at present was no larger and in some parts very much smaller than it was before the war. They could not deal with this question at all without discriminating very carefully between the relatively small minority in respect of whom there was a real chance of doing something in the directions to which the Bishop of Exeter had alluded, and the very much larger proportion who certainly would not be dealt with satisfactorily by any of those methods. The first main factor in the making of vagrants was that most of them liked the life. They got sufficient food and shelter, because a certain number of people gave them what they wanted without any real inquiry into their circumstances or their needs. He did not think it was too much to say that among the persons who came before a public body as vagrants there was not more than 1 in 500 to whom help could effectually be given. There were only two main lines of remedy. The first was to direct public attention to the matter, and secondly to persuade the public that they might really leave vagrants to the care of the authorities or of voluntary bodies trained and equipped to deal with them effectually, and that alms personally given did harm and not good. But, of course, it was extraordinarily difficult to do this. To have institutions up and down the country to receive these tramps was not really going to be helpful. The kind of person likely to commit himself to the care of an institution of that sort for an indefinite time under discipline was very rare indeed

"INFAMOUS AND INTOLERABLE" CONDITIONS.

The Bishop of SOUTHWARK said it was stated in the report that "in a certain number of casual wards the conditions now existing are infamous and intolerable." Those were very strong words, and they were all the stronger because the report throughout was so restrained in its language. It was surely impossible to allow these conditions to continue without immediate action. It was stated in the report that out of 592 casuals examined 93 were found to be mentally defective, 32 were insane, and 34 were suffering from some form of psychoneurosis. If this proportion was applied to the 12,000 casuals to be found in the casual wards and on the roads on any one night, something like 1800 people among them were mentally defective, 600 were insane, and 600 others were suffering from some kind of mental defect. The committee reported that it was quite convinced that there was an appreciable number of casuals who were certifiable under the Lunacy Acts. The committee recommended that the officer in charge of the wards should report to the authorities any case in which there appeared to be some mental illness, and further that the medical officer of health should, at least once a month, pay an unexpected visit to the casual ward and medically inspect its inmates to see whether any of them were suffering from mental illness. That recommendation could be carried out without legislation, and he was anxious to know if any definite steps had been taken in that respect. He was also anxious to know what steps were being taken to coördinate the different areas dealing with this problem. Great emphasis was laid throughout the report on the fact that usually one found ineffective administration when the unit of administration was small, and good administration when the area of administration was large.

GOVERNMENT'S REPLY.

Lord MARLEY (Under Secretary for War), replying on behalf of the Government, said that the Minister of Health had been very much concerned with the Vagrancy Report, and he felt compelled to obtain the names of the particular wards pilloried as being "infamous and intolerable." The Minister had taken immediate action to secure improvement in those particular wards. On August 13th of this year the Minister issued a circular to all county councils, county boroughs, and joint vagrancy committees, and with it he enclosed a copy of the Vagrancy Report. In the circular the Minister called attention to Part IV. of the report, in which a judgment was expressed as to the badness of the conditions now prevailing in certain casual wards, which the Minister had noted with the deepest concern and regret. He was confident that the new authorities would agree with him that no branch of public administration ought to be allowed to consider itself liable to such reproaches, and he hoped immediate and vigorous steps would be taken for a general overhaul of casual ward arrangements so that decent and seemly provision might be made everywhere for the accommodation of casuals. The circular went on to say that the Minister had instructed the general inspectors to coöperate closely with local authorities and to keep the Ministry of Health informed of progress in securing the needed improvements; and the Minister had it in mind in the autumn to detail an officer or officers for special work in this matter. There were 12 general inspectors, including a chief inspector, now engaged in this work, and there were also four special assistant inspectors. Since the issue of the circular the Minister had learned with very great satisfaction that many councils and joint vagrancy committees had themselves undertaken an examination of the wards, and had set about the work of improving the conditions found to be unsatisfactory. In regard to the number of joint vagrancy committees, 18 such combinations had already been created by statutory orders, and 43 administrative counties and 67 county boroughs had been combined into those 18 joint vagrancy committees. Proposals were now being considered for five more joint vagrancy committees, which would include 11 additional administrative counties and 16 county boroughs. The Minister of Health had in draft a new Order which would regulate the relief of casuals and would embody such recommendations of the Vagrancy Report as could be made effective by means of an Order. With this Order the Minister of Health intended to issue a circular drawing attention to such other recommendations in the report as could not be dealt with suitably by regulation. The new Order would be issued in a very few days. All vagrancy committees constituted by the grouping of counties and county boroughs had power to contribute by annual subscription towards the support and maintenance of any institution which appeared to them calculated to render useful aid in the administration of relief of casuals. Under this head they could, by way of subscription, encourage the formation of training homes for casuals and others. He thought it would be better to segregate mental defectives in homes where they could be dealt with from an educational point of view.

The Bishop of EXETER withdrew his motion for Papers.

PHARMACY AND POISONS BILL.

In the House of Lords on Dec. 17th Lord MARLEY introduced the Pharmacy and Poisons Bill, which was read a first time.

THE CHRISTMAS ADJOURNMENT.

Both Houses of Parliament adjourned on Friday, Dec. 19th, for the Christmas recess, until Jan. 20th. In the House of Lords the Royal Assent was given to a number of Acts, including the National Health Insurance (Prolongation of Insurance) Act.

HOUSE OF COMMONS.

MONDAY, DEC. 15TH.

Pulmonary Tuberculosis and Disablement Pensions.

Dr. MORRIS-JONES asked the Minister of Pensions whether he was aware that in certain cases of pulmonary tuberculosis, although there might be extensive physical signs in the chest, a decision had been given that this did not necessarily indicate a high degree of disablement; that the presence of tubercle bacilli in the sputum did not mean that the man was totally disabled; that pensioners suffering from tubercular disease of the lungs were cut down in their assessments when it was found they were at work; and whether this had been done on the instructions of his department.—Mr. ROBERTS replied: The hon. Member would appear to have been misinformed as to the tenor of the Ministry's medical instructions. Assessment of pension is based on the degree of physical loss or incapacity sustained by an officer or a man in consequence of a particular injury or disease, not merely on the clinical signs present in the case. The statements referred to in the first two parts of the question, while conveying an obvious application of this principle, are far from adequately representing the principles on which medical officers of the Ministry work. With regard to the statement in the third paragraph of the question, it is never the case that an assessment is reduced simply because the man is at work, though the extent, if any, to which the man has shown himself capable of regular work is necessarily some evidence of incapacity.

WEDNESDAY, DEC. 17TH.

The Government and Factory Legislation.

Mr. MANDER asked the Home Secretary when it was proposed to introduce the Factories Bill.—Mr. CLYNES replied: I regret I am not in a position to make any statement on this point.

Prison Administration.

Dr. PHILLIPS asked the Home Secretary whether he had had under consideration the appointment of a departmental committee to investigate the administration of prisons; and, if so, whether he proposed to set up such a committee.—Mr. CLYNES replied: I propose to set up at an early date a committee to investigate the problem of persistent offenders who return to prison repeatedly, and pending the result of this investigation it would not be desirable to appoint a committee of inquiry into other aspects of the prison question.

Capital Punishment.

Mr. HACKING asked the Home Secretary what action he proposed to take in connexion with the report from the Select Committee on Capital Punishment.—Mr. CLYNES replied: Before I can make any statement on a subject of such vital importance I must have time to consider the report in all its bearings and all the issues involved.

Sterilisation of the Mentally Unfit.

Mr. SORENSEN asked the Minister of Health whether he had considered resolutions requesting the appointment of an inquiry into sterilisation in relation to the mentally unfit; how many local authorities had endorsed these resolutions; and what he proposed to do in the matter.—Mr. GREENWOOD replied: Twenty-one local authorities have endorsed resolutions in favour of an investigation of this kind; but, as I explained in reply to a question on Nov. 27th, the issue is not one which can suitably be made the subject of a separate inquiry.

Infected Mutton from South America.

Mr. THORNE asked the Minister of Health if he was aware that considerable quantities of imported mutton and lamb from the Argentine Republic and Chili were infected with caseous lymphadenitis, and were escaping inspection at the ports and reaching butchers' shops, and that in order to evade inspection quantities of legs, shoulders, sides, saddles, and other parts, cut from diseased carcasses, were being imported; and if he would take steps to prohibit the importation of mutton from these countries other than in carcass, and order a more rigid examination of all imports, and insist that the work of cutting the glands was carried out by skilled butchers.—Mr. GREENWOOD replied: I am aware that caseous lymphadenitis is found in a certain proportion of carcasses of mutton and lamb imported from the countries referred to. The normal practice is to make a preliminary examination at the port of 10 per cent. of each consignment of whole carcasses, and to examine the remaining 90 per cent. either at the port or elsewhere if the result of the preliminary examination shows this to be desirable. I do not think it necessary to recommend any modification of this practice. At a conference recently held between medical officers of the ports principally concerned and officers of my Department it was decided that imports of mutton and lamb from South American countries should receive special attention, and that severed parts of carcasses should in all cases be given complete examination. I am considering whether any further conditions should be laid down in connexion with the importation of severed parts of carcasses. I understand that the work of cutting the glands is at all ports entrusted to persons who have experience of the work, and I do not think it necessary to make any special recommendation on this point.

Cheese Wrapped in Tinfoil.

Major GEORGE DAVIES asked the Minister of Health whether his attention had been drawn to a special investigation, made by the medical officer of health to the Lambeth Borough Council, into the possibilities of tin poisoning from cheese wrapped in tinfoil, the analyst reporting that the result of his investigation indicated that cheese so prepared in this country could be regarded as perfectly safe for human consumption; and whether he would take all steps to relieve public anxiety on the matter.—Mr. GREENWOOD replied: I have received a communication from the Lambeth Borough Council enclosing a report in which the medical officer of health makes the statement referred to. Some samples of cheese prepared in this country have been found to be unduly contaminated by the tinfoil in which they were wrapped, but I understand that the industry is aware of the importance of reducing the extent of the contamination to the lowest possible limit, and is making efforts to achieve this end. In the meantime I am keeping the matter under observation, but I do not think it necessary at present to make any further statement.

A National Maternity Service.

Viscountess ASTOR asked the Minister of Health whether it was intended to introduce legislation making provision for a national maternity service.—Mr. GREENWOOD replied: I am sending the noble lady a copy of a circular and memorandum which I have recently issued to local authorities on the subject of maternal mortality. As stated in the circular, the Government have decided to undertake negotiations with the various authorities concerned with a view to formulating a scheme on a national basis for the care of maternity. Such negotiations are a necessary preliminary to the introduction of legislation for this purpose.

Lieut.-Colonel FREMANTLE asked the Minister of Health if, before any scheme for a national maternity service was formulated, he would confer with the midwives through the Incorporated Midwives' Institute and the Queen's Institute of District Nursing, as the respective bodies mainly representing and employing them, as well as with bodies representing the medical profession and other interests concerned.—Mr. GREENWOOD replied: I will consider the suggestions made by the hon. and gallant Member.

Wandle Valley Hospital Accommodation.

Mr. MILLS asked the Minister of Health if he was now in a position to sanction the Wandle Valley hospital construction, Surrey.—Mr. GREENWOOD replied: I have directed a public inquiry to be held into the application in question. I shall not be in a position to give my decision on the application until I have considered the report on the inquiry, but there will be no avoidable delay.

Sulphur Dioxide in Fruit Pulp.

Viscount ELMLEY asked the Minister of Agriculture (1) when he would introduce legislation amending the part of the Merchandise Marks Act relating to the amount of sulphur dioxide permissible in imported pulped fruit, and (2) if he would make an order to compel jam manufacturers to label their products to show whether they were made of preserved fruit.—Dr. ADDISON replied: The regulation of preservatives in foodstuffs is provided for under the Public Health Acts, under which it would be impossible to discriminate between imported and home products. I am, however, carefully considering whether, and in what way, steps can be taken to indicate to the consumer that the jam he is purchasing is, or is not, made entirely from home-grown fruit.

Extension of Westminster Hospital.

Lieut.-Colonel FREMANTLE asked the First Commissioner of Works if, in view of the necessity of the Westminster Hospital concentrating outlying departments and extending on the adjacent site now occupied by the Stationery Office, he would consider helping Parliament to act in support of its local hospital by assisting it to acquire the site of the Stationery Office on easy terms, partly in exchange for outlying sites and leases now held by the hospital.—Mr. LANSBURY replied: I regret that it is not possible for me to assist the Westminster Hospital in the manner suggested.

Volunteers and Poison Gas Experiments.

Mr. FREEMAN asked the Secretary for War the number of volunteers who had submitted to poison gas experiments; and what fund, if any, existed to compensate them in case of accident or injury or their dependents in case of death.—Mr. T. SHAW replied: Since Jan. 1st, 1929, some 520 volunteers have undergone tests with the object of proving the efficacy of preventive and curative treatment for skin burns and of confirming the adequacy of the protection afforded by respirators. Many of these volunteers have undergone more than one test. Every care is taken to ensure that the test involves no risk to the health of the volunteers, but, if an injury was sustained, it would be dealt with as attributable to the Service, and such compensation would be paid from Army funds as the ordinary regulations provide.

Prevention of Influenza.

Mr. LOUIS SMITH asked the Home Secretary whether, in view of the sanction he had given to by-laws enabling municipalities to prohibit the attendance of children at places of entertainment when there was local influenza, he could state how he proposed to define the term influenza.—Mr. CLYNES replied: I am not aware that any by-laws have been made on this subject. The hon. Member may be referring to a condition that may be attached by a licensing authority to the grant of a licence under the Cinematograph Act, 1909. I understand that a number of such licensing authorities have made it their practice to attach a condition designed to exclude children from premises licensed under the Act during an epidemic of infectious disease. But these conditions do not require my sanction, and any question regarding their validity or interpretation is a matter for the courts.

FRIDAY, DEC. 19TH.

Purity of Agricultural Produce.

Brigadier-General CLIFTON-BROWN asked the Minister of Health whether, in order to improve the position of home-grown agricultural produce on the home market, he would take steps to ensure that imported food, milk, and other dairy produce were subject to regulations concerning quality and purity similar to those enforced in the case of home produce.—Mr. GREENWOOD replied: Regulations concerning the quality and purity of food are made on public health grounds or otherwise to protect the interests of the consumer. In general, therefore, home-produced and imported foods are subject to the same requirements. In many respects the actual control of imported foods is the stricter since these articles are subject to inspection at the time of importation as well as at the time of exposure for sale. As regards imported milk, the quantity of which is insignificant, it would not be practicable to enforce the detailed requirements of the Milk and Dairies Order, and in lieu thereof a strict bacteriological condition is imposed which does not apply to home-produced milk.

Post-vaccinal Encephalitis.

Mr. FREEMAN asked the Minister of Health how many of the 97 deaths from post-vaccinal encephalitis, referred to on page 73 of the annual report of the chief medical officer for 1929, appeared in the annual statistical reviews of the Registrar-General as caused by vaccination.—Mr. GREENWOOD replied: Of the 97 deaths in question 30 have been classified to vaccinia, and have appeared under that heading in the annual statistical reviews of the Registrar-General.

Mr. FREEMAN asked the Minister of Health whether, in view of the continued occurrence of deaths from post-vaccinal encephalitis after the use of Government lymph extracted from the vesicles of rabbits, he would consider the desirability of dispensing with the use of these animals in connexion with the preparation of the Government lymph supplies.—Mr. GREENWOOD replied: This question has been fully considered, but as I am advised that there is no evidence that post-vaccinal encephalitis is attributable to the use of rabbits in connexion with the preparation of lymph, I do not consider that any change in the present practice of the Government lymph establishment is necessary.

MEDICAL NEWS

University of Oxford.

On Dec. 17th the following degrees were conferred:—

D.M.—R. S. Creed and E. B. Strauss.

B.M.—Anne D. M. Adams, F. R. Crookes, H. R. J. Donald, H. C. Harley, R. S. Harrison, M. A. Hatt, J. M. Lees, Q. St. L. Myles, N. C. Parfit, and F. M. Trefusis.

University of Cambridge.

On Dec. 19th the following degrees were conferred:—

M.B. & B.Chir.—D. W. Bawtree, A. T. Curnow, and W. R. H. Pooler.

M.B.—S. E. F. Gooding and W. E. Mashiter.

B.Chir.—D. G. Macdonald and F. G. Booker.

University of Birmingham.

On Dec. 19th the following degrees were conferred:—

M.D.—Felix Smith.

M.B. & Ch.B.—R. H. Fooks, C. E. Moorhead, and J. V. Walker.

L.D.S.—R. H. Allen, R. A. Cohen, Flora M. Grant, R. C. Lewis, R. E. Marlow, H. E. Munro, and Queenie A. L. Whitmore.

University of Liverpool.

At recent examinations the following candidates were successful:—

M.CH. ORTH.

A. C. Armstrong, J. C. Drummond, L. W. N. Gibson, M. K. Hussein, P. Roux, and V. J. M. Taylor.

M.D.

G. S. Clouston, T. B. Davie, J. H. Follows, J. Hatton, D. E. P. Pritchard, J. E. Wallace, and Kathleen M. Ward.

FINAL EXAMINATION FOR M.B. AND CH.B.

Part A (1924 Regulations).—F. C. Angior, Mary F. Lacey, F. T. B. Lovegrove, and D. I. A. Williams.

(In individual subjects only).—G. R. Critien, D. J. Hoskingson, C. Y. Howarth, and Beatrice L. H. Sergeant.

Part B.—*C. G. Burgess, J. M. Erskine-Young, and H. E. C. Sutton.

* Distinction in Surgery.

Part I (1923 Regulations).—R. Fairhurst.

Part III.—H. F. Cohen, F. J. H. Crawford, A. Gardner, Teresa Lightbound, and V. T. Parkinson.

DIPLOMA IN TROPICAL MEDICINE.

K. N. Bagchi, L. B. Bier, J. Caplan, D. S. Chowdhary, T. H. Davey, L. M. Ghosh, F. Hawking, L. J. A Loewenthal, D. McElwee, J. B. MacKie, Y. B. Mangrulkar, W-K. Miau, H. W. Mulligan, F. O'Driscoll, M. Singh, J. K. Sung, G. Verghese, J. L. A. Webster, and J. Willoughby.

University of London.

The title of Emeritus Professor of Fine Art in the University has been conferred on Mr. Henry Tonks, F.R.C.S., on his retirement from the Slade Chair of Fine Art at University College.

The degree of D.Sc. has been conferred on Mr. G. F. Marrian (in biochemistry) and Mr. Philip Eggleton (in physiology).

On the recommendation of the Board of Management of the London School of Hygiene and Tropical Medicine, Sir George Newman has been appointed Heath Clark lecturer for 1931.

Royal College of Surgeons of Edinburgh.

At a meeting of the College on Dec. 17th, with Dr. J. Haig Ferguson in the chair, the following 30 successful candidates (out of 95 entered) who passed the requisite examinations between Sept. 29th and Oct. 7th, were admitted to the Fellowship:—

Philip Jacob Alpers, Sheikh Amir-ud-Din, Ahmad El-Sayed Ali Ammar, Thomas Cecil Baker, Diana Jean Kinloch Beck, Evert Frederick Birkenstock, William Mark Brown, Alfred Rainald Keith Burne, William John Anson Coldstream, James Cook, George Harvie Duncan, Harry Medcalf Fisher, Ian Comyn Fraser, Phillip Gibbin, Laurence Samuel Henry, Bruce Ernest Lawrence, Daniel Richard Lewis, William Laurence Macdonald, Hamish Grant McPherson, Alexander Mayne Martell, Alexander Smith Morton, James Duncan Murdoch, Thomas Alexander Ogilvie, Doddaballapur Hari Rao, Walter Ogilvy Reid, Kiranla, Sen, Tarachand Dayasing Shahani, Robert Sharpe Venfers Bryan Williams, and Thomas Isaac Williams.

Fulham Power Station Inquiry.

At an inquiry which is being held by the Electricity Commissioners into the application of the Fulham Borough Council for consent to extend their generating station in Townmead-road, Mr. J. H. Ryder, consulting engineer to the Council, described apparatus for the elimination of sulphur fumes by the treatment of flue gases with water, and said he believed it was possible to eliminate sulphur from the gases at Fulham. Evidence was given by Sir Frank Baines of the increasing damage to public buildings in London due to smoke pollution in the past few years. Dr. F. Barrie Lambert, on behalf of the L.C.C. Public Health Committee, said that when the Council in 1927 withdrew its opposition to the Battersea proposal it had not a full appreciation of the possible danger from sulphur fumes. The danger of mass production was not then considered. Mr. J. E. Singleton,

K.C., in opening opposition on behalf of the L.C.C., and three associated councils, said that no one doubted the existence of danger to health and buildings if there was further pollution of the atmosphere. At Battersea there had been a great advance in preventing the evolution of oxides of sulphur, and he asked for an opportunity of seeing these tests in operation before leave was granted for extension at Fulham. Dr. J. S. Owens, speaking for the Department of Scientific and Industrial Research, said that in the presence of sulphuric acid particles fog was formed at a lower relative humidity; the smaller the particles the more effective they were in producing fog. He went on to consider the possible risk from inversion of the usual sequence of air temperature. Normally this fell as one went from the ground upwards, but there was always inversion over the top of a fog which increased the likelihood of flue gases sinking to the ground, and inversion increased this danger. If the whole of the flue gases from the proposed station settled down over an area (say) of a square mile, they would cover it to a depth of 30 feet. On behalf of the L.C.C. Mr. Trevor Watson, K.C., stated the conditions which the Council thought should be imposed if the application were granted, the first of these being that the sulphur content of the effluent gases should not exceed gr. 0·02 per cubic foot. Mr. J. A. Robertson, consulting engineer, said that a small number of stations spread over a large city did not in his opinion cause so much damage through sulphur dioxide as one big station, but he believed the solution of the problem of eliminating sulphur fumes was nearer than many people thought. Dr. W. Allen Daley, principal medical officer to the L.C.C. General Public Health Branch, said that the poor people in the vicinity of the proposed power station would continue to use coal fires unless electricity was particularly cheap. He regarded as satisfactory a limitation of SO_2 in the atmosphere to gr. 0·02 per cubic foot. Mr. Tyldesley Jones, K.C., for the Fulham Borough Council, remarked that wherever the station was put the sulphur nuisance must be prevented. The Fulham Council had adopted the Modave purifying plant which they believed to be still further capable of improvement, but should it be found unsatisfactory it could be scrapped. Everything which could reduce the domestic coal consumption would tend to mitigate the mischief of smoke pollution. The L.C.C., he remarked, was having to extend the boiler capacity of its Greenwich station regardless of the consequences in the matter of sulphur content. The public inquiry closed on Dec. 20th.

Instruction for D.P.H.

A three-months' course of lectures and demonstrations on Clinical Practice and in Hospital Administration will be given at the North-Eastern Hospital, St. Ann's-road, Tottenham, by Dr. F. H. Thomson, the medical superintendent, on Mondays and Wednesdays at 4.45 P.M. and alternate Saturdays at 11 A.M., from Jan. 5th. Application should be made to the Medical Officer of Health, London County Council, Public Health Department (Special Hospitals), Victoria Embankment, E.C. 4.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.

FRIDAY, Jan. 2nd, 1931.—4 P.M., Mr. J. D. McLaggan: Atrophic Rhinitis.

Appointments

HAINWORTH, E. M., M.D. Lond., F.R.C.S. Eng., has been appointed a Medical Referee under the Workmen's Compensation Act for the Districts of the Beverley, Bridlington, Goole, Great Driffield, Kingston-upon-Hull, Pocklington, and Selby County Courts.

Royal United Hospital, Bath: KINDERSLEY, C. E., F.R.C.S. Eng., Surgeon, and MITCHELL, D. A., M.D. Lond., F.R.C.S. Edin., Surgeon in charge of the Gynæcological Department.

Cardiff Royal Infirmary: WADE, J. O. D., M.S. Lond., F.R.C.S. Eng., and HARRIES, D. J., M.D., B.S. Lond., F.R.C.S. Eng., Honorary Surgeons.

Certifying Surgeons under the Factory and Workshop Acts: BARBER, G. O., L.R.C.P. Lond., M.R.C.S. (Dunmow); DAVIS, E. C., M.B., Ch.B. Edin. (Llandyssul, (Cardigan); and CARMICHAEL, R. McL., M.B., Ch.B. Glasg. (New Tredegar, Mon.).

Vacancies

For further information refer to the advertisement columns.

Brighton, Royal Sussex County Hospital.—H.S. £150.

Burnley, Victoria Hospital.—Two H.S.'s. Each at rate of £150.

Bury St. Edmunds, West Suffolk General Hospital.—Jun. Res. M.O. £150.

Chesterfield and North Derbyshire Royal Hospital.—H.S.'s. All at rate of £100–£175.

Dumfries, Crichton Royal Mental Hospital.—Locum Tenens Clin. Pathologist. 7 gns. weekly.

Dunedin, New Zealand, Otago Hospital Board.—Radio-Therapeutist. £1000.

Finsbury Borough Council.—Asst. M.O.H. £750.

Hertford County Hospital.—Hon. Asst. Surg. Also H.P. At rate of £150.

Hospital of St. John and St. Elizabeth, 60, Grove End-road, St. John's Wood, N.W.—Radiologist.

Hospital for Sick Children, Great Ormond-street, W.C.—Part-time Jun. Cas. O. At rate of £150.

Hull Royal Infirmary, Sutton Branch.—H.P. At rate of £160.

Indian Medical Service.—Commissions.

Leamington Spa, Warneford General Hospital.—Res. H.P. and H.S. Each £165.

Liverpool, David Lewis Northern Hospital.—Two Hon. M.O.'s for Ear, Nose, and Throat and Dermatological Departments.

Liverpool Sanatorium, Delamere Forest, Frodsham.—Asst. Med. Supt. £250.

Mansfield, Notts, Harlow Woods, Orthopædic Hospital.—Res. Surg. O. £275.

Margate; Royal Sea Bathing Hospital, &c.—H.S. At rate of £200.

Middlesex C.C.—Dist. M.O. for Tottenham. £180. Also Public Vaccinator.

National Hospital, Queen-square.—Hon. Surg. Asst. Also Hon. Asst. Surg.

Nelson Hospital, Merton, S.W.—Res. M.O. £100.

Nottingham General Dispensary.—Res. Surgeon. £250.

Nottingham General Hospital.—H.S. At rate of £150.

Poplar Hospital for Accidents, East India Dock-road, E.—Sec. Res. O. £175.

Prince of Wales's General Hospital, N.—Asst. Pathologist. £200.

Rotherham Hospital.—H.P. £180.

Sheffield, Jessop Hospital for Women.—Three Asst. H.S.'s. Each at rate of £100.

Sheffield Royal Infirmary.—H.P., H.S., Asst. Aural and Ophth. H.S. Also Asst. Cas. O. All at rate of £80.

Swansea County Borough.—Asst. M.O. £600.

Swansea Hospital.—Sen. Res. O. £300.

Wallasey Victoria Central Hospital.—Jun. H.S. At rate of £100.

Walsall General Hospital.—H.S. At rate of £150.

Weston-super-Mare General Hospital.—Res. H.S. At rate of £150.

Worcester County and City Mental Hospital, Powick.—Jun. Asst. M.O. £350.

Wrexham and East Denbighshire War Memorial Hospital.—Two Res. H.S.'s. Each at rate of £150.

Births, Marriages, and Deaths

BIRTHS.

PHILIP.—On Dec. 16th, at Maldon Court, Maldon, Essex, the wife of J. L. R. Philip, M.B., Ch.B., of a son.

MARRIAGES.

DICKIE—KIRBY.—On Dec. 17th, 1930, at Christ Church, Rawalpindi, by the Rev. J. G. Lister, M.A., Major Ronald Stevenson Dickie, R.A.M.C., younger son of the Rev. W. S. Dickie and Mrs. Dickie, Saltcoats, Ayrshire, to Violet Eleanor, younger daughter of Colonel J. T. Kirby, Indian Army, and Mrs. Kirby.

DEATHS.

HICKMAN.—On Dec. 18th, Lieutenant-Colonel James Hickman, R.A.M.C. (retired).

SIMEON.—On Dec. 15th, Edward A. Simeon, M.R.C.S., L.R.C.P., of Hoe-street, Walthamstow, E., aged 70.

STOWERS.—On Dec. 17th, 1930, at 38, Regent's Park-road, N.W.1, James Herbert Stowers, M.D., of 128, Harley-street, W.1 in his 80th year, peacefully in his sleep.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

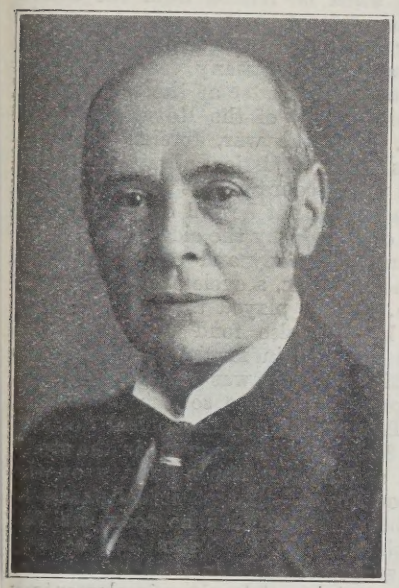
DONATIONS AND BEQUESTS.—Mr. Robert Slater Boddington, J.P., of Manchester, left £1000 to the Manchester Northern Hospital for Women and Children, to endow a bed in that hospital.—Mr. George Fowler Hutchings, of Weston-super-Mare, left £1500 to the Bristol Royal Infirmary to endow a bed in the women's ward, and £100 each to the Bristol Orthopædic Hospital for Crippled Children and the Bristol Blind Asylum.

OBITUARY

JAMES HERBERT STOWERS, M.D. Brux., M.R.C.S. Eng.

THE death of Dr. Stowers on Dec. 17th, in his eightieth year, removes the senior representative of British dermatology. With him there passes the last of those of who lived and flourished with Jonathan Hutchinson, Colcott Fox, Radcliffe Crocker, and Malcolm Morris.

James Herbert Stowers was the fourth son of Nowell Stowers, M.R.C.S., who practised in Kennington. He was educated at St. Bartholomew's Hospital, whence he qualified in 1873, and among the teachers of whom he often spoke with admiration were Luther Holden and James Paget. During the next few years he gained a varied experience as ophthalmic house surgeon, registrar, dermatological assistant, and administrator of anæsthetics at Bart.'s, and resident medical officer at the Evelina Hospital for Sick Children. He entered general practice in Shrewsbury, but soon returned to London to specialise in dermatology, and was appointed physician to St. John's Hospital, Leicester-square. He also joined the staff of the North-West London Hospital, where he remained at work until over 40 years later, when it was amalgamated with the Hampstead General Hospital. Most of his professional work was done at the St. John's Hospital and at the North-West London. The former institution owes him a special debt, for it was largely due to his initiative and tact that the post-war reorganisation of its medical staff was made possible, and its important position as a teaching centre was retained and enhanced. His enterprise and effort in founding the London School of Dermatology was recognised by his colleagues, and some years ago their appreciation was shown by a complimentary dinner, at which he received well-deserved congratulation. Dr. Stowers was a member and corresponding member of various British and foreign dermatological societies, and a past-president of the British Dermatological Society and the Dermatological Section of the Royal Society of Medicine. Outside his own specialty, also, he was well known, for he belonged to many different societies which reflected the wide range of his interests. Despite numerous appointments to hospitals and institutions he found time to take part in local affairs and politics, while in later years his experience was always at the service of the London and Counties Medical Protection Society. As a member of the Council for over 30 years he showed a keen regard for medical ethics, and his consistent work was of much value to the society. His attention to detail, the clarity and precision of his utterances, and his personal charm would have been assets in many walks of life, and they found full scope in the career he had chosen.



DR. STOWERS.

Photograph: Elliott & Fry.

During the late war Dr. Stowers took charge of the Department for Diseases of the Skin and Venereal Disease at University College Hospital. He married Henrietta, daughter of Edward Shepherd, and she is left with two sons, one of whom, Dr. Raymond Stowers, is in active medical practice.

CHARLES ALGERNON STIDSTON, D.S.O., M.D. Lond.

WE have to record that Mr. C. A. Stidston, surgeon to the Royal Hospital, Wolverhampton, died on Dec. 15th in his fiftieth year. Son of the late Charles Stidston, of Plymouth, he received his medical education at St. Bartholomew's Hospital where he gained the Foster Prize and the Wix Prize. He went to Wolverhampton in 1907 as resident medical officer of the General, now the Royal Hospital, and was appointed honorary assistant surgeon two years later, becoming full surgeon in 1920. On the outbreak of war in 1914 Mr. Stidston was called up with his Field Ambulance, the 2/3rd North Midland (Territorial Force). He served throughout the war and was for 18 months at the front in France. He was in command of his field ambulance during the difficult and anxious fighting which followed the battle of Cambrai, and for services in the field on this and other occasions was awarded the D.S.O. At the end of the war he retired with the rank of lieut.-colonel and resumed his practice at Wolverhampton.

We owe the following appreciation to one of his hospital colleagues. "Charles Algernon Stidston, whose loss is deplored not only by his colleagues and friends but by the inhabitants of Wolverhampton and South Staffordshire among whom he lived and practised for 21 years, was a man of original personality and varied gifts. His abounding vitality, his charm of manner, and breadth of sympathy earned him the devotion of his patients, rich and poor alike. He had a lively and spontaneous wit and a gift of expression both in speech and writing which were the delight of his friends. He could be pungent on occasion but even his victims were ready to forgive him for his wit, and enjoy a laugh against themselves. He was the warmest, the most faithful, the most generous of friends. He had his fierce hatreds too, for there was nothing half-hearted about him. To serve a friend no effort and no sacrifice were too great. With equal prodigality he spent himself in serving many who had no claim but their needs and his own generosity.

"At the Royal Hospital he threw himself into his work with the zest and devotion which he displayed in all his pursuits. Although he had a large and very successful general practice, it was his ambition and intention to devote himself entirely to surgery as soon as circumstances permitted. It was a tragic disappointment to find himself disabled by the illness to which he finally succumbed, at the very

moment when he saw the prospect of realising his ambition. For five months he lay ill and almost helpless. He never murmured or complained, and bore himself throughout with characteristic dignity and fortitude. Courage, generosity, and modesty were parts of his nature and they displayed themselves equally in war and in peace."

Mr. Stidston leaves a widow with one daughter.

CHARLES HENRY PHILLIPS, M.D. Durh., F.R.F.P.S. Glasg.

Dr. C. H. Phillips died on Nov. 23rd at Bournemouth where he had lived for some years in retirement. Born in 1847, he was first trained for a business career, but his attention was diverted towards medicine and he qualified from Owens College, Manchester, in 1875. After working for some time at Bury in Lancashire, he went to the Potteries in 1879, and was for 36 years visiting medical officer to the Joint Infectious Diseases Hospital at Bucknall, Stoke-on-Trent, and to the Small-pox Hospital at Bagnall. It was largely through his efforts that these institutions grew from small beginnings to their present state of efficiency. "Dr. Phillips was never one to acclaim his own achievements," writes a colleague, "but to those who had the privilege of his friendship, as I had for a period of 28 years, his sterling character, as well as his great professional abilities have made a lasting impression. He had a quiet dignity of manner associated with infinite patience—qualities which endeared him to all his patients, both in hospital and in the large private practice he carried on for so many years. He never spared himself in the carrying out of any of his duties, and his special skill in midwifery, gained from much experience, often led fellow practitioners to seek his advice and assistance, which was always given ungrudgingly. For many years he took an active part in municipal affairs in Hanley, and was appointed a justice of the peace; further, he was chairman of the local Panel Committee under the National Health Insurance Act. He retired from practice in 1923, but until the end took the same keen interest in all matters connected with the medical profession. His latter years were shadowed by bereavement and an increasing loss of sight, but he bore his afflictions with fortitude and cheerfulness."

FREDERICK WILLIAM BENNETT, M.D. Lond., B.Sc. Manch.

WE have already recorded the death of Dr. Frederick Bennett at Leicester on Dec. 3rd at the age of 70. The following notice is contributed by two of his colleagues:—

Dr. Bennett studied medicine at Owens College. He became M.R.C.S. in 1883, M.B. Lond., with honours in medicine, in 1884, and M.D. a year later. After having held house appointments in Manchester hospitals, he started practice in Leicester, and his first appointment was hon. assistant physician to the infirmary. But he was attracted to what was then a new specialty, that of laryngology. A few of the larger hospitals were creating departments for the treatment of diseases of the throat, nose, and ear, but many of those who applied for such appointments did so only to get a footing on the hospital staff and resigned them as soon as possible for general surgery. As there was very little teaching to be had in this country, Bennett, like many others, went abroad and studied in Vienna. On his return he was made the first aural surgeon to the infirmary. He remained faithful to his choice and continued to hold this appointment for nearly 30 years.

The way of a pioneer is always difficult. The hospital provided instruments and accommodation (of a sort) for his out-patients, but no house surgeon attended and no nurse assisted. Bennett engaged one of the latter from outside at his own expense. Very few beds were at his disposal, an odd one here in a medical ward, there in a surgical, and scattered throughout the hospital. Only minor operations were permitted to the aural surgeon; tonsils and adenoids, polyp, and so forth. Any such as the opening of the mastoid bone were claimed by the general surgeon as his prerogative. It is a tribute to Bennett's skill, his energy, his personal charm, his relations with his colleagues, and his unfailing interest in his work, that when he retired from the active staff he left a department well equipped, greatly enlarged, and fully recognised as an important branch of the hospital practice. For many years he was a member and a constant attender at the meetings of the Section of Laryngology of the Royal Society of Medicine. When, after the war, foreign members were excluded, his sense of justice, always high, led him to resign. On that account he was not well known to the younger generation, but he will be remembered with the kindliest of feelings by the older men.

Bennett was a man of many and varied interests. He was keenly fond of music, a cycle of "The Ring" was a joy to him, and he played the 'cello in local orchestras. But he was also fond of science and 20 years after he qualified in medicine he took the degree of B.Sc. His great love was geology. He was, until his death, president of the section of geology in the Leicester Literary and Philosophical Society. Many holidays in Switzerland were spent in the study of glacial action, and he was the authority on the rocks of Charnwood Forest—that perpetual puzzle to geologists. In addition to all this he took his full share as a prominent citizen. Years ago he was a member of the school board. In 1891 he drew up the scheme for the training of teachers in elementary science, which was then just permitted to be taught in elementary schools, real pioneer work. As a coöpted member of the city museum and library committee he worked for years. As one of the earliest subscribers to the local university college, and as a member of its council, he worked hard to encourage it, as well as frequently supporting it financially. Such were his pleasures, real joys to him.

Mrs. Bennett died about three years ago. They leave two daughters.

A. L. McC.
A. V. C.

THOMAS VINCENT CAMPBELL, M.B. Edin.

Dr. T. V. Campbell, who died at Edinburgh on Dec. 16th, had retired from active missionary service in South India in 1920. Born at Londonderry in 1863, he graduated at Edinburgh in 1888 and was appointed medical missionary at Jammalamadugu, in the Cuddapah district of South India, two years later. Owing to ill-health he had to return to England for a time, but in 1912 he and his wife—formerly Dr. F. G. Longbottom, of Halifax—returned to India to take charge of a new hospital, founded in memory of Dr. Wardlaw Thompson, at Chikka Pallapura, where they together established a medical mission work as successful as that at Jammalamadugu. In 1908 Dr. Campbell was awarded the Kaisar-i-Hind Medal for public services. Mrs. Campbell survives her husband with a son and two daughters.

NOTES, COMMENTS, AND ABSTRACTS

RADIATION FROM WIRELESS VALVES.

By H. M. S. Turner, M.D., F.R.S. Edin.,
late examiner in physiology, cairo university.

In high-power wireless valves used for transmission the heat generated may be so great that ordinary glass is unable to withstand it. To overcome this difficulty the valves may be provided with a water-jacket or a highly refractory substance may be used instead of glass, with air cooling. In certain valves fused silica is used for this purpose. Valves of the latter type in use appeared to me to possess all the necessary factors for the production of X rays, to the passage of which fused silica would offer comparatively little opacity. I decided to expose some X ray films to the emanations from such valves. Eastman Kodak Duplitized films were used. Each was enclosed in its light-proof container and one film, in its container, was enclosed in an envelope made from thick sheet-lead on the front of which a cross had been cut out after the manner of a stencil. (Fig. 1.) In front of the others letters cut from sheet-lead were closely applied. (Figs. 2 and 3.)

In the early days of X ray apparatus an induction coil giving about a 12-inch spark was used with ordinary Crookes's tubes. The tubes I used then were about the size of a Jaffa orange and the induction coil was fitted with a spring contact-breaker such as is found on a "buzzer." At that time we knew nothing of the properties of the rays and had to learn the correct length of exposure by trial and error. The efficiency of such an apparatus may be judged when it is mentioned that exposures as long as two hours were sometimes given to skiagraph a chest. Fifteen minutes and half an hour were quite common.

As wireless transmission valves are not designed to produce X rays, it was decided to start with a minimum exposure of two hours, and to place the films at a distance of eight inches from the valves. Six valves in a "bank" were used for the experiment and during the exposure the voltage and milliampèrage were recorded and marked on each film. All the films were exposed simultaneously, and the time when the exposure was commenced was also recorded on the film after development—viz., at 10 hrs. 43 mins. P.M. The voltage during exposure was uniformly 4000 and the milliampèremeter reading was 160 to 170. I was informed that owing to a transformer being out of action the voltage was much lower than it should have been and that the normal reading would be about 18,000 v.

The results of the experiment will be seen from the accompanying films, which prove quite definitely not only that the valves are radio-active, but that the emissions appeared to be quite appreciable in quantity—so much so that the question of possible effect upon attendants arises. It is customary to protect the transmission gear by a safety-fence, provided with one or more gates giving access to the apparatus. These gates operate switches, so that if an individual passes through the gate whilst transmission is in progress the circuit is broken and the current is cut off. The fence does not allow approach nearer than about 15 or 16 feet and, as the effect of any radio-active emissions would vary inversely as the square of the distance, the cumulative effect, if any, may be small. Nevertheless, with an individual working constantly in the vicinity, even at a distance of 16 feet or over, the possibility is one to be borne in mind.

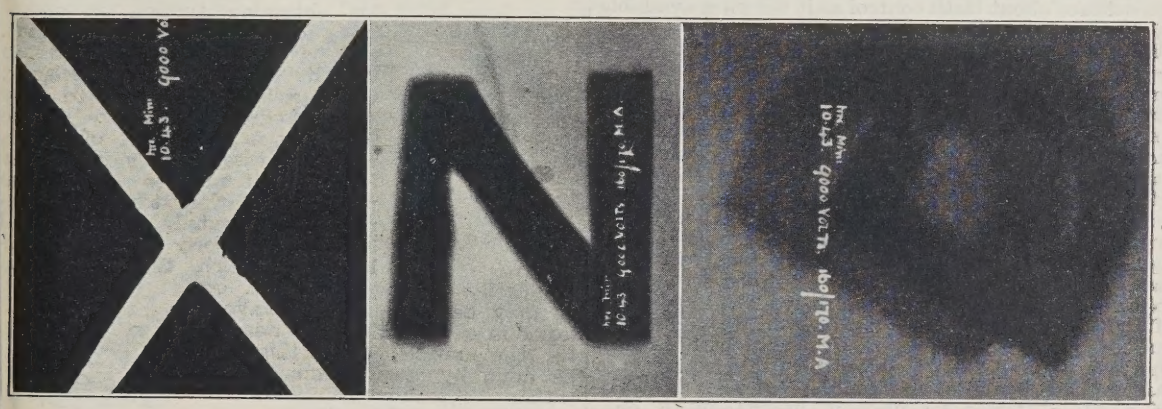
I was unable to get any history of erythema or any other indication of effect from the attendants I saw; but it should be realised that one does occasionally meet with individuals who are inclined to attribute many things to "wireless." For example, I remember many years ago in the days of the old rotary spark-gap that there was quite a common idea prevalent among the men that working near the spark-gap made them impotent—for which effect there could have been no possible cause. Had such a complaint been made by a man working in the vicinity of a bank of valves, such as those which produced the accompanying films, one might have given a certain amount of credence to it. For obvious reasons no leading questions were asked. Doubtless every new occupation will have its own peculiar diseases. Perfect protection would be given if the valves were screened with metal, or possibly even with lead glass screens of suitable proportions.

I am unable to give any information as to the precise nature of the emanations. I do not know their power of penetration, for I had no means at hand for measuring it; neither can I estimate the quantity, say, in terms of pastille doses. I simply desire to record the fact that skiagrams can be taken by the agency of such valves.

Although the exposures were made simultaneously under exactly the same conditions of distance, voltage, and milliampèrage—except as regards the length of exposure—each film was exposed to a different valve. Therefore any slight variations in the quality of the respective negatives may depend upon differences in the individual valves. Each valve has a very robust filament, which is heavily thoriated.

Some of the films (e.g., Fig. 3) show a double

FIGS. 1 2 3



Exposure 2 hours. 3 hours. 6 hours.

image. This is due to rays from an adjacent valve striking the film at an angle and giving a "localisation" effect. In the film showing the letter "N" the shadow of the string by which the sheet lead letter was supported can be seen.

THE PROTEASES OF PLANTS.

A PAMPHLET by Prof. S. H. Vines, intended to serve as a reply to R. Willstätter, has reached us.[1] The author's experiments, carried out during the years 1897–1910 upon the proteolytic enzymes of plants, led him to conclude that there existed two distinct enzymes; one was a protein-splitting enzyme or peptase which yielded albumoses and peptones, the other a proteose-splitting enzyme, comparable with Cohnheim's erepsin, which, acting on proteoses, converts these into amino-acids—notably, tryptophane. Willstätter contests this view, and considers the two digestive processes to be effected by one and the same protease or proteinase. Prof. Vines's argument is that it does not follow that a peptone-splitting erepsin may not occur in plants because no such enzyme can be certified in animals, and asserts that confirmation of his views will shortly be supplied by Prof. Nag, working at the Bose Research Institute, Calcutta.

BIRTH CONTROL: METHODS AND RESULTS.

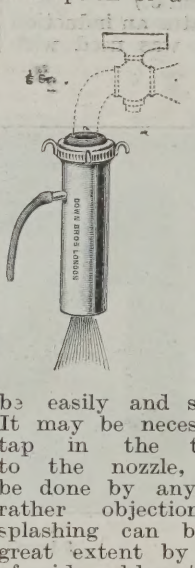
AT the Population Conference which met at Geneva in September, 1927, a group was formed with the object of collecting and impartially summarising every year information of statistical and medical importance about birth control as it becomes available in the course of each year. Contributions from different countries are edited by Dr. C. P. Blacker, who is honorary medical secretary of the Birth Control Investigations Committee. The third issue of the summary, which has recently appeared,[2] contains contributions from three countries—Denmark, Germany, and Great Britain—the last being much the fullest. In all three a description appears of the Gräfenberg ring. Dr. Gräfenberg himself describes his revised method in some detail, but does not analyse this now considerable accumulation of figures. Dr. Norman Haire states that only in three cases out of 200 were there untoward symptoms following the insertion of the ring. The experience of Dr. Leunbach (Denmark), however, does not bear out these favourable results. In a series of 177 cases, the ring fell out on 20 occasions. It descended as far as the external os in three and, though properly in position, failed to prevent pregnancy in one. Dr. Leunbach adds "moreover, the method is far from harmless. In many cases it has been necessary to remove the ring on account of metritis and parametritis or persistent bleeding from the uterus."

Certain interesting statistical results are reported from this country, which go to show how much the existing contraceptive methods leave to be desired. The results of Mrs. Florence's investigations at the Cambridge Women's Welfare Centre[3] are summarised in some detail. Among the most notable of her findings is the frequency of the failure of coitus interruptus among clinic patients. Thus, of the 118 patients who, before coming to the clinic, had made use of coitus interruptus, no less than 105 had found the method to fail. Among these 105 women there had been 409 pregnancies. Though these figures must not be taken as representing the success of coitus interruptus in the population as a whole (in so far as those who use the method successfully would not attend a birth control clinic), they are nevertheless significant. Statistical evidence is also adduced showing that much difference of opinion exists among medical authorities as to what is the optimum size of an occlusive pessary for normal women, and what is, on the whole, the most satisfactory make of pessary for average women. At the birth control clinics whose results are here reported the pessaries most used are the Mensinga and the Dumas. The prorace cervical cap is little used.

Interesting researches on chemical spermaticides and on the effects of these on the uterus and vagina of animals are summarised by Dr. Blacker in his report for Great Britain. Dr. J. R. Baker, working in the zoological laboratory of the University of Oxford, has shown that the assumption that because a given substance is a good germicide it is also a good spermaticide is wholly fallacious. Dr. H. C. Carleton and Dr. H. S. Florey have shown that most of the spermaticides on the market have no appreciable effect on the endometrium and vaginal mucous membrane of laboratory animals, even when applied in relatively large quantities. These investigators have also shown that the ascent of spermatozoa into the uterine cavity is accomplished through the intrinsic powers of locomotion of the spermatozoa rather than by the mechanical sucking action of the uterus itself.

A HYDROSTATIC PUMP ATTACHMENT.

Dr. G. A. Metcalfe has sent us an illustrated description of a modification which he has made, with the help of Messrs. Down Bros., Ltd., London, S.E. 1, in the hydrostatic pump supplied by them. He says: For some time past I have been using a hydrostatic pump for obtaining suction in operations on the nose and throat, and have been greatly impressed by its value and efficiency. One great drawback to the usual hydrostatic pump is the fact that a good head of water, which is essential for its proper function, tends to blow the pump off the tap. In the pump illustrated, four metal hooks have been brazed to the lead by which the pump can be easily and securely tied on. It may be necessary to have a tap in the theatre adapted to the nozzle, but this can be done by any plumber. The rather objectionable noise of splashing can be silenced to a great extent by fixing a length of wide rubber tubing to the outlet and allowing it to open under water in a basin.



OUR OLDEST SUBSCRIBER.

Sir Temulji Bhicaji Nariman, M.R.C.P. Edin., writes from Bombay to say that he has been a subscriber to THE LANCET for the last 61 years without intermission, an achievement which he regards "as a record, if not for England, at least for India." Sir Temulji, who was born in 1858, celebrated his jubilee in the medical profession eight years ago, and is planning to have a diamond jubilee in 1932.

AVERTIN IN OPHTHALMOLOGY.

IN an annotation with this title on p. 1357 of our last issue it was stated that the amount of avertin used "should never exceed 1·0 g. per kg. of body-weight." The quantity mentioned should have been ten times less—namely, 0·1 g. per kg.

THE Anglo-French Drug Company (238a, Gray's Inn-road, London, W.C. 1) have sent us a copy of their block diary for 1931, measuring 6 by 4½ inches, and showing a page to a day. It serves as a useful accessory to the writing table. The list of pharmaceutical products formerly attached to the inside of the front cover is not now included.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY LIMITED

(FOUNDED 1892)

Registered Office: VICTORY HOUSE, LEICESTER SQUARE, W.C.2.

Telegrams: "MEDICAVERO, WESTRAND, LONDON." *Telephone:* REGENT 0611.

President: Sir JOHN ROSE BRADFORD, K.C.M.G., C.B., C.B.E., M.D., P.R.C.P., F.R.S.
Treasurer and Chairman of Council: C. M. FEGEN, M.R.C.S., L.R.C.P., D.P.H.
Trustees for the Reserve Fund:
Rt. Hon. LORD DAWSON, P.C., G.C.V.O., K.C.B., M.D., F.R.C.P. Sir JOHN ROSE BRADFORD, K.C.M.G., C.B., C.B.E., M.D., P.R.C.P., F.R.S. Sir HARRY BALDWIN, C.V.O., M.R.C.S., L.D.S.

The Society was founded for the following purposes: To protect, support, and safeguard the character and interests of legally qualified Medical and Dental Practitioners; to advise and assist Members of the Society in matters affecting their professional character and interests; and to indemnify them in regard to actions, etc., undertaken on their behalf.

SUBSCRIPTIONS:—There is an entrance fee of 10s., and an Annual Subscription of £1.

The Invested Funds of the Society exceed £43,000. The Society is fully insured to an unlimited extent against all adverse costs and damages which may be awarded against Members in any action which the Society undertakes on their behalf.

Forms of application for Membership and full particulars may be obtained from the Secretaries at the above address.

OXFORD MEDICAL PUBLICATIONS

An entirely new issue of great importance to Teachers and Students:—

HISTOLOGY FOR MEDICAL STUDENTS

By **H. HARTRIDGE**, M.A., M.D., Sc.D., M.R.C.P., F.R.S.,
Professor of Physiology, University of London, at St. Bartholomew's Medical College;

and **F. HAYNES**, M.A.,
Demonstrator of Histology, University of London, at St. Bartholomew's Medical College.

Some of the subjects covered:—Histology of the Cell—Epithelia and Endothelia—Connective Tissues—Blood and Accessory Tissues—Muscles, Heart, etc.—Nervous Tissues—Nervous System—Organs of Special Sensibility—Respiratory System—Digestive System—Glands—Urino-Genital System.

Some features of special interest:—Microscopic and microtomic technique—Anatomical references—Tissue identification—Tissue culture and grafting—Intra-vitam staining—Micro-injection and micro-dissection—Blood-platelet enumeration—Reticulo-endothelial system—Differentiation of structure.

This book has been planned to anticipate and overcome the difficulties of the student. Thus, the illustrations (which all occupy full pages) have been so placed that the corresponding text is invariably opposite them—no searching back or forth is needed. The magnification and staining method used for each specimen is indicated, and a list is given of the staining reactions exhibited by all classes of tissues.

The index of 30 pages, each in two columns, calls for special mention, as it is also in part a glossary, giving a direct rendering of technical terms into commoner language, and vice versa.

A system is described whereby the student may keep constant watch on his own progress and simultaneously study his specimens and test his powers of indentification. The authors' practical experience of examinational requirements in English schools of medicine has enabled them successfully to take a middle course between undue compression and the inclusion of unnecessary matter.

J. & A. CHURCHILL

AN ESTABLISHED BOOK and A NEW BOOK BY

W. H. C. ROMANIS and PHILIP H. MITCHINER

Surgeons, St. Thomas's Hospital.

THE SCIENCE & PRACTICE OF SURGERY

Third Edition. 716 Illus. Two Vols. 28s.; post. 1s. 3d.

SURGICAL EMERGENCIES IN PRACTICE

158 Illustrations. 18s.; post. 9d.

London: J. & A. Churchill, 40, Gloucester Place, Portman Square, W.1.

From EDWARD ARNOLD & CO.'s List

NEW (SECOND) EDITION ***COMPLETELY REVISED***

TEXT-BOOK OF THE
SURGICAL DYSPEPSIAS

Edited by **A. J. WALTON,** M.S., F.R.C.S., B.Sc., M.B., *Surgeon (with care of out-patients) to the London Hospital.* **Second Edition.** xii+720 pages. 286 illustrations, 2 coloured plates. **42s.** net.

British Journal of Surgery (of first edition).—"Mr. Walton's excellent book fills an undoubted hiatus, in that it embraces almost all the surgical abdominal conditions associated with dyspepsia, and gives the most carefully selected extracts in regard to their etiology and pathology; it fills a place which could only be furnished otherwise by a perusal of at least a dozen works or monographs of 'specialists' in the various dyspepsias."

INSOMNIA
An Outline for the Practitioner

By H. CRICHTON-MILLER, M.D., Hon. Director, Tavistock Square Clinic, London. **10s. 6d.** net.

"The work is to be cordially recommended. It serves as an admirable introduction and up-to-date review of a difficult subject."—LANCET.

Principles of BACTERIOLOGY AND IMMUNITY

By Professor W. W. C. TOPLEY, M.A., B.Ch., M.R.C.S., F.R.C.P., F.R.S., and Professor G. S. WILSON, M.D., B.S., D.P.H., of the London School of Hygiene and Tropical Medicine. Two Volumes. 1360 pages. 242 illustrations. **50s.** net.

A SYSTEM OF CLINICAL MEDICINE

By THOMAS DIXON SAVILL, M.D.Lond. *New (Eighth) Edition.* Revised by Dr. AGNES SAVILL and Others. xxviii+1016 pages. 4 coloured plates and 176 illustrations. **28s.** net.

A Text-book of SURGICAL DIAGNOSIS
With Contributions by 33 eminent Authors.

Edited by A. J. WALTON, M.S., F.R.C.S. Two Volumes, xvi+1122 pages, 570 illustrations. **63s.** net.

Garrod, Batten & Thursfield's DISEASES OF CHILDREN

SECOND EDITION, with Contributions by 36 Authors. Edited by HUGH THURSFIELD, D.M., M.A., F.R.C.P., and DONALD PATERSON, M.D., F.R.C.P., Physicians to the Hospital for Sick Children, Great Ormond Street. xii+1106 pages, 250 illustrations. **45s.** net.

DISEASES OF WOMEN

By TEN TEACHERS. Edited by COMYNS BERKELEY, M.A., M.D., F.R.C.P., F.R.C.S., H. RUSSELL ANDREWS, M.D., B.S., F.R.C.P., and J. S. FAIRBAIRN, M.A., B.M., B.C., F.R.C.P. *New (Fourth) Edition,* completely Revised. xii+588 pages, 8 plates and 186 illustrations. *Price reduced to* **18s.** *net.*

Write for Detailed Prospectuses

LONDON: EDWARD ARNOLD & CO., 41-43, MADDOX STREET, W.1

PUBLISHED NOVEMBER 6th

DIAGNOSIS OF MENTAL DEFICIENCY

By HENRY HERD, M.A., M.B., Ch.B.,

Senior Assistant School Medical Inspector, City of Manchester Education Committee; Certifying Medical Officer to the Lancashire Mental Deficiency Authority.

284 pp. Demy 8vo. Fully illustrated with 39 Half-tone and 11 Line Blocks.

Published at **12/6** net; postage 6d.

Dr. Herd's book appears exactly when the questions raised by the recent Report of the Mental Deficiency Committee call for consideration from the medical profession and the public alike. The book provides for the medical practitioner the means to diagnose the presence of mental deficiency and indicates the real significance of moral defect. For the instruction of the psychologist it sets out in orderly form the tests of intelligence and temperament, explaining by illustrative cases how mental deficiency can be graded; for the special information of the public the statutory duties imposed and the powers conferred by recent Acts of Parliament are included. A valuable arrangement of material puts in the front an essay on the psychology of the normal subject, it being recognised that the greatest difficulties in social life arise in so-called border-cases, where the amount of lapse into abnormality has to be evaluated.

The book will prove useful to the whole medical profession; first to those whose duty it may be on any day to give counsel to the heads of families, and secondly to those whose routine business it is to issue official certificates. Further, by its pages school teachers will be helped to understand the difficulties of backward pupils, and all social workers will find much assistance in their work by consulting the section on general psychology and the discussion of moral cases.

THE MUSEUM GALLERIES

have pleasure in announcing that they will shortly open the well-known Galleries,

No. 7 HAYMARKET,

where for the past Century many famous master-pieces have been exhibited.

The Studios at 53, Short's Gardens, Drury Lane, will remain, and when you are at the Galleries, facilities will be afforded you to visit the Studios to see the Artists engaged upon taking impressions in Colour and in Monochrome by hand, from hand-engraved Mezzotint and Stipple plates by leading Engravers.

Announcement of the actual opening Exhibition will be made in the near future.

CONTRACEPTION (BIRTH CONTROL)
ITS THEORY, HISTORY AND PRACTICE.
A Manual for the Medical and Legal Professions.
By
MARIE CARMICHAEL STOPES, D.Sc., etc.,
Fellow of University College, London.
Introductions by the late Prof. Sir WILLIAM BAYLISS, F.R.S., Sir JAMES BARR, M.D., and Dr. C. ROLLESTON.
A few press opinions of the 1st Edition:
MEDICAL TIMES.—"The book is unique and marks a new era."
THE LANCET.—"Much of the evidence contained in the book is quite unobtainable elsewhere."
Sir Archdall Reid in NATURE.—"Some such book as this had to be written, and this is very well written."
MED. REV.—"Should be read by all interested in racial welfare."
This book is the first manual on the subject, and is packed with both helpful and interesting matter and much that is new and noteworthy. London:
Bale & Danielsson, Ltd., 83-91, Gt. Titchfield-st., Oxford-st., W.1

Wayne Babcock's
Text-Book of Surgery

"Takes a distinguished place among the many general textbooks that are available. It is designed both for the student and the practitioner, as the author believes that, with the increase of clinical teaching and the declining importance of systematic lectures, the student must turn more to his reading for his theoretic background."
—BRIT. MED. JOUR.

By W. WAYNE BABCOCK, M.D., Professor of Surgery, Temple University, Philadelphia. Octavo of 1367 pages with 1050 illustrations, 9 in colours. Cloth, 45s. net.

MacCallum's
Text-Book of Pathology

"No doubt this book has often been taken down from the laboratory shelf to verify some small point, not to be replaced immediately the information sought has been obtained; it is apt to beguile the reader, enticing him to some stimulating thought. It teaches ideas rather than facts."—BRIT. MED. JOUR.

By W. G. MACCALLUM, M.D., Professor of Pathology and Bacteriology, Johns Hopkins University. New (Fourth) Edition. Octavo of 1177 pages. 606 original illustrations, 50 in colours. Cloth, 45s. net.

Pneumonia and Influenza

William H. Peters, M. D., *Admitting Physician Camp for Consumptives, State of Rhode Island, Providence, R. I.:* "VALENTINE'S MEAT-JUICE was the only nourishment retained by my five-year-old daughter during an attack of Pneumonia. She is still taking it and gaining strength. I consider that it saved her life and believe it to be the best product of its kind on the market."

Cavalier Dr. Enrico Ballerini, *Late Surgeon to the Hospital of Rome, Italy:* "I have used VALENTINE'S MEAT-JUICE in the treatment of patients and also personally after having been very ill with Influenza, and I must say it is an excellent tonic in conditions of great organic weakness. It is also very agreeable. I have prescribed it with the greatest satisfaction for convalescents and invalids restricted to a liquid diet."

For Sale by European and American Chemists and Druggists.

ASTHMA

There are certain types of chronic asthmatics who require relief of their paroxysms. While adrenalin is generally effective it must be given hypodermically and its action is short lived. Vapo-Cresolene (specially prepared cresols of coal tar) vapourized in the bedroom at night will give the desired relief. The patient is not disturbed as he breathes the medicated air of the bedroom.

This antiseptic vapour is particularly effective in bronchial ailments accompanied with cough and difficult breathing—as bronchitis, whooping cough, spasmodic croup.

Vapo-Cresolene

PUBLISHED RECENTLY

DIAGNOSIS OF MENTAL DEFICIENCY

By HENRY HERD, M.A., M.B., Ch.B.,

Senior Assistant School Medical Inspector, City of Manchester Education Committee; Certifying Medical Officer to the Lancashire Mental Deficiency Authority.

284 pp. Demy 8vo. Fully illustrated with 39 Half-tone and 12 Line Blocks.

Published at **12/6** net; postage 6d.

Dr. Herd's book appears exactly when the questions raised by the recent Report of the Mental Deficiency Committee call for consideration from the medical profession and the public alike. The book provides for the medical practitioner the means to diagnose the presence of mental deficiency and indicates the real significance of moral defect. For the instruction of the psychologist it sets out in orderly form the tests of intelligence and temperament, explaining by illustrative cases how mental deficiency can be graded; for the special information of the public the statutory duties imposed and the powers conferred by recent Acts of Parliament are included. A valuable arrangement of material puts in the front an essay on the psychology of the normal subject, it being recognised that the greatest difficulties in social life arise in so-called border-cases, where the amount of lapse into abnormality has to be evaluated.

The book will prove useful to the whole medical profession; first to those whose duty it may be on any day to give counsel to the heads of families, and secondly to those whose routine business it is to issue official certificates. Further, by its pages school teachers will be helped to understand the difficulties of backward pupils, and all social workers will find much assistance in their work by consulting the section on general psychology and the discussion of moral cases.

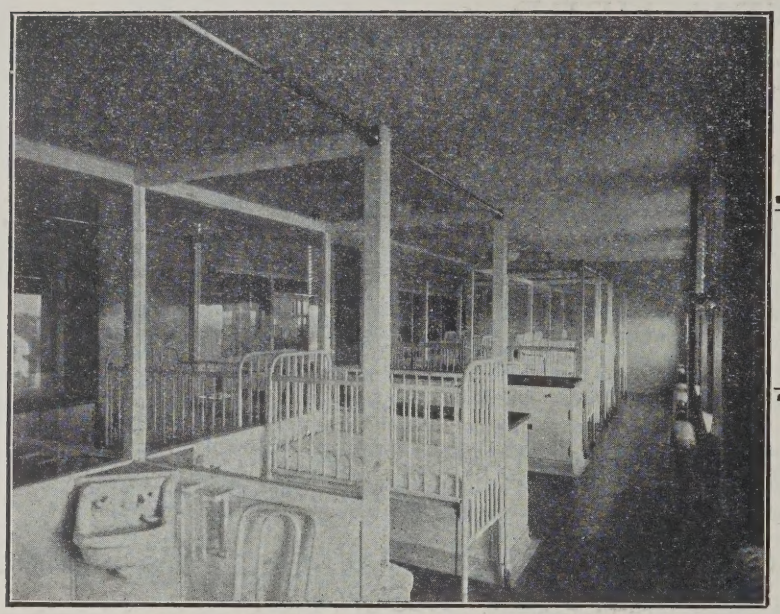
NOISE has no place in a hospital . .



This Children's Ward is fitted with "AKOUSTIKOS."

"AKOUSTIKOS" *offers you a scientific method of ending the noise nuisance*

It is generally agreed that noise in hospitals is a menace to the health of patients and a trial to the nerves of the staff. The activity which causes that noise is unavoidable, but the excessive reverberation and clatter can easily be reduced to an unimportant minimum by "AKOUSTIKOS" Sound Control Methods.

"AKOUSTIKOS" engineers attack all sound control problems and use materials made specifically for acoustical purposes.

The result is that where this system is in use disturbing noise is entirely eliminated. The "AKOUSTIKOS" (Johns-Manville) Sound-Absorbing Treatment is applicable to all parts of hospitals. Corridors, wards, delivery and operating rooms, kitchens and other service departments, can be freed of the reverberation so disturbing to patients.

The "AKOUSTIKOS" (Johns-Manville) Sound-Absorbing Treatment can be finished with sanitary washable enamels without appreciable reduction of efficiency.

We welcome enquiries from hospital officials, and a conference concerning Sound Control involves no obligation.

Please write to us.

"AKOUSTIKOS"

DEAF DOCTORS
AND DEAF PATIENTS

have proved "ARDENTE" a boon—a Heart Specialist whose work is so dependent on his hearing writes: "'Ardente' is a godsend to me"; without "ARDENTE" he is, to all intents and purposes, "stone" deaf; with "ARDENTE" he carries on his work — what better testimony to "ARDENTE" merit?

Mr. Dent makes a Stethoscope specially for deaf Do ors—the only one of its kind, which is widely used and praised. Doctors whose work lies amongst the deaf prefer to prescribe "ARDENTE" because they know that "ARDENTE" is the only individual method in the whole deaf world (no mass production way can ever succeed with human disabilities) and they know what "ARDENTE" service stands for to the deaf. Many who are deaf use "ARDENTE."

"ARDENTE" is entirely different and uncopyable and succeeds in widely differing cases. A full range covers the needs of those suffering from varying forms and degrees of deafness and tinnitus. Minutely adjusted to the requirements of the case for young, middle-aged, or old, and so sensitive as to have the desired effect even in middle-ear and nerve cases, bringing into action and stimulating the auditory system, enabling it to function naturally and saving atrophy. "ARDENTE" can be used or not at will, and is sold under guarantee.

"ARDENTE" is the choice of Doctor and patient—only after test and hearing, or from prescription or particulars, is "ARDENTE" fitted, toned, adjusted, and supplied.

Tests and demonstrations given at Doctors', patients', or our addresses, without fee or obligation.

MUCOUS AND OTHER FORMS OF COLITIS

CONDITIONS of Colitis occur at all ages, and lead to much suffering, ill-health and chronic invalidism. They are caused by a great variety of bacteria, which, owing to a loss of resistance on the part of the mucous membrane of the colon, maintain a chronic infection, with inflammation of this portion of the intestinal tract.

Vaccine therapy is frequently tried in this condition with disappointing results, as it is pure chance if the causative organism is isolated from the host of bacteria present.

The rational treatment is obviously to administer an efficient germicide which will attack and destroy *all* the bacteria present. Kerol is the one substance which possesses this power, and its administration has cured many a case of mucous colitis.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession

NEUROTIC CARDIAC PAIN

may or may not have an immediate serious cardiac import, but *it is always serious to the patient*, both in its physical and its mental effects. Most of these types of precordial pain, moreover, are caused in some way by the heart itself, and are attended by some degree of palpitation and arrhythmia.

ANASARCIN RELIEVES

the majority of these patients. Indeed, in many cases it acts like magic in dispelling these distressing precordial pains, and restoring comfort and well-being to the patient.

NO UNTOWARD EFFECTS

need be feared from the use of Anasarcin in these cases. It is a rational, physiologic heart tonic, steadying the beat, dilating the arterioles, and toning the muscle. You can regulate its dosage to a nicety, avoiding all cumulative and other undesirable effects.

Permit us to send you a copy of our booklet, "Anasarcin in Disorders of Heart and Vascular System."
Also Sample of Anasarcin for your trial.

WHY HOVIS MATTERS

Largest Content of VITAMIN B

Important Conclusions

The question as to what form of bread provides the essential Vitamin B most completely and economically has now been settled by independent experiments.

It is shown that in 100 g. dried bread the content of Vitamin B in milling products and yeast is :—

White Bread . . .	200
Wholemeal Bread . .	1,450
Hovis Germ Bread . .	2,600

That the presence of the Vitamin is essential actively to promote health in adults and sturdy growth in children, is generally accepted from continued observation.

Wheat is rich in Vitamin B and the germ is the richest part.

Hovis is made from the white flour with the germ added. This gives Hovis its pre-eminent position as a basic ration.

You obtain—as demonstrated by series of experiments by independent investigators—a greater active nutritive value from Hovis than from any other cereal.

You need a smaller amount of Hovis than any other bread for the proportion of nourishment received. This is a matter of very practical importance especially where, as in so many homes and institutions, bread of necessity forms a large part of the daily diet.

With children especially a far larger amount of Vitamin B is supplied to them when fed on Hovis.

One slice of Hovis weighing 1 oz. contains as much Vitamin as 2 oz. of Wholemeal and as 5 to 6 g. of fresh yeast.

Everybody likes it, another practical consideration, especially with children, and it is digested nearly as easily as white bread and much more so than wholemeal.

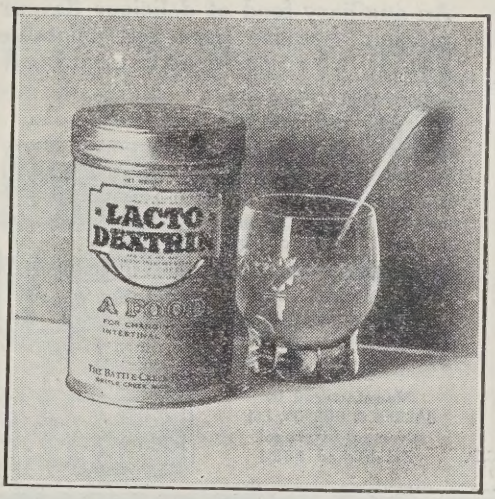
Best Bakers Bake it

HOVIS LTD. LONDON & MACCLESFIELD

FOR . . .

changing the intestinal flora . . . supplying bulk and lubrication



Lactose 73%, dextrine 25%—that is the proportion in which these carbohydrates are combined in this new food for changing the intestinal flora. Both are more slowly absorbed than other carbohydrates, and both are able to reach the colon in sufficient quantity to cause a luxuriant growth of protective flora. An acid reaction of the intestinal contents unfavourable to toxic organisms is thus produced—Lacto-Dextrin being highly efficient in promoting the growth and development of both B. acidophilus and B. bifidus in the colon. In this pure carbohydrate food both lactose and dextrin are presented in a palatable and agreeable combination.

PSYLLA

—an accessory for use in conjunction with Lacto-Dextrin

Where bulk and lubrication of the intestinal tract is also required, the use of BATTLE CREEK Psylla (Plantago Psyllium) is invaluable as an accessory. The small brown seed when in contact with water swells into a soft gelatinous mass and acts most effectively both as an emollient and intestinal evacuant.

Samples and literature of both these intestinal products will be sent to members of the Medical Profession on request to Coates & Cooper, 41, Great Tower Street, London, E.C.3, Sole Distributing Agents for the United Kingdom and Irish Free State.

HOW GIBBS HELPS THE DOCTO

Gibbs teaches the Golden Rule
PREVENTION IS BETTER THAN CURE

Prevention of decay is the keynote of all Gibbs advertising and propaganda. Gibbs try to teach the Public to regard the loss of even one tooth as a tragedy of the first magnitude.

By the constant reiteration of a few simple, wholesome precepts, Gibbs endeavour to impress strongly upon the Public the vital necessity for absolute cleanness of the mouth as a first principle in preserving the teeth. Following that, any authoritative utterances by Doctors or Dentists upon any phase of teeth preservation, are given the widest possible publicity by Gibbs.

The House of Gibbs welcome, at all times, suggestions from Doctors or Dentists as to any special phase of dental prophylaxis which, in the Doctor's or Dentist's opinion, should be specially emphasised at any particular time or in an particular locality.

Gibbs constantly remind the Public that a little car and thoughtfulness in matters of dental hygien is repaid a thousandfold in returns of beauty health, happiness and business and social success.

The Doctor and Dentist are always presented a the Highest Authorities upon all matters connecte with the teeth. Very largely as a result of Gibb propaganda, there is an increasing acceptanc upon the part of the Public, of any and all advic or instruction given by the Medical Profession.

Thus, in so far as they are able, Gibbs ar working hand in hand with the Doctor and Den tist, looking forward to that day when the greate part of all dental work will be purely preventive

GIBBS DENTURE TABLET

Gibbs new Denture Tablet is for cleaning Dental Plates, Bridgework (both gold and vulcanite) and artificial teeth. It gives a high polish, removes stains, makes plate or teeth sterile and antiseptic without in anyway injuring the softest gold or the finest vulcanite or platinum. The formula has been submitted to and approved by important members of the Medical Profession.

BOOTS PURE DRUG CO. LIMITED
NOTTINGHAM ENGLAND

THE therapeutic value of Cod Liver Oil is fully appreciated by the Medical Profession. It is recognised for its specific action (due to its high content of Vitamins A and D) in rickets, affections of the chest, and diseases arising out of malnutrition. Boots Reinforced Cod Liver Oil is a biologically controlled preparation containing five times the amount of Vitamin D in addition to the normal amount of Vitamin A. The advantage of a concentrated oil needing only a fifth of the usual dose will be particularly valuable. Four fluid ounces of Reinforced Cod Liver Oil —Boots, contain the same amount of Vitamin D as one pint of the finest Norwegian oil.

In 4-oz. bottles, **2/6.**

R AND C

Specially indicated in

NEPHRITIS - URÆMIA - ECLAMPSIA - ALBUMINURIA

and allied conditions.

PROMPT and proper diagnosis of kidney conditions is necessary in cases of Bright's disease and all types of renal disorders. In nine cases out of ten the administration of a specific capable of producing real results in compensating for the loss of kidney function is also necessary.

For more than a quarter of a century Nephritin has been a sheet anchor to physicians in treating such disorders. Nephritin Tablets induce a marked increase in nitrogenous waste elimination. They reactivate the cells of the kidney, increase urinary secretion, and induce a greater output of urea.

Given in sufficient dosage these tablets produce marked results, and restoration to normal is quickly stimulated. They are invaluable also as a prophylactic in renal complications of infectious diseases and during pregnancy. The tablets are composed of the hormones of the normal kidney as they appear in nature—*absolutely unaltered.*

Case of Broncho-pneumonia—girl aged 10

Chart showing fall in temperature after a single injection of S.U.P. 36

In Febrile Inflammatory Conditions

In all those infections which, starting with the common cold, accompanied by high temperature, pass on with rapidity to influenza, broncho-pneumonia or pneumonia, the timely administration of S.U.P. 36, before complications have developed, serves to abort the attack and to promote a quick and uneventful recovery.

If diagnosis is not established until further infection has supervened, the administration of S.U.P. 36 produces immediate effects which have been described as "*little short of marvellous*"—symptomatic relief is experienced, normal temperature is restored, and the duration of the disease is reduced by more than one half.

VERONIGEN

A liquid preparation of the Hypnotic Barbitone or Diethyl-barbituric acid has long been desired as a useful means of procuring sleep. When given in reasonable doses it is claimed that it does not produce any toxic symptoms whatever, nor is cumulative in action, and in ordinary cases of insomnia one fluid drachm of VERONIGEN is sufficient dose for an adult. As a preventive of post-operative vomiting, one to two fluid drachms of VERONIGEN may be given one and a half to two hours before general anæsthesia is produced, and as a result much less of the anæsthetic is required. As BARBITONE has a slight diuretic action, the mixture can be used more safely than other hypnotics when the heart is weak. Where sleeplessness is a concomitant of pain, rest and relief can frequently be obtained by the administration of one drachm of VERONIGEN and two drachms of ELIXIR ACID. ACETO-SALICYLIC (Hewlett's).

DOSE FOR ADULTS.—One fluid drachm diluted, one hour before going to bed.
For Nervous Sleeplessness in Children.—10 to 20 minims diluted.

VERONIGEN. Price **10/6** per lb.

In Sepsis and Dental Prophylaxis

In the report of the Milroy Lecture delivered before the Royal College of Physicians of London (*Lancet*, April 5th, 1930, p. 773), attention was directed to the fundamental causes of sepsis and dental caries.

It is recommended that "*we should follow* **that more excellent way**. . . . *not only must growing children have a sufficient diet containing Vitamin D, but that proper maternal feeding with a diet containing the same vitamin is essential while the child is yet unborn if he is to produce not only perfect deciduous but also permanent teeth.*"

Clinical evidence proves that, even after dental caries has begun, the administration of Vitamin D can arrest the process of decay.

The best means of providing a sufficiency of Vitamin D is through the medium of Radiostol, either as a standardised solution alone or, combined with Vitamin A, as Radiostoleum or, with Vitamins A, B_1 and B_2 as

THE BRITISH DRUG HOUSES LTD. LONDON N-1 V.P./104

Alasil

Analgesic Antipyretic Sedative

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"ALASIL" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill-conditions of the gastric tract.

"ALASIL" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time.

Analgesic, Antipyretic, and Sedative, "ALASIL" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

A. WANDER, Ltd., Manufacturing Chemists,
184, Queen's Gate, London, S.W.7

M.296

ALOCOL

Colloidal Hydroxide of Aluminium

For Chronic Irritations of the Gastric Mucosa

WHEN alkaline therapy is indicated "Alocol" is the preferred form of treatment. Its advantages over the usual oxides and alkalis are manifest. Whilst the preparations in common use give momentary relief to painful symptoms they aggravate the morbid condition. Consequently such remedies are contra-indicated, especially in stubborn, chronic cases.

The action of "Alocol" is superior in every way, because it does not merely confine itself to combating the symptoms of the trouble, but attacks the origin itself.

"Alocol" fixes the acid, not by neutralization, but by adsorption. It relieves pain, is slightly astringent and limits the acid secretions. "Alocol" is always well borne; no harmful secondary action follows its administration, and its therapeutic effect is not diminished with prolonged use.

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.

ARTERIO-SCLEROSIS

AND

HIGH ARTERIAL TENSION

The preparation of Chlorophyll developed by Dr. E. Buergi, Professor of Medicine at the University of Berne, has been found most valuable in cases of cardiac weakness, even where other treatments have failed to give satisfactory results. Its action was observed over a series of cases in which the heart's action had been impaired by arterio-sclerosis and other complaints. Reports (1) (2) show the preparation effectively strengthens the cardiac action and dilates the peripheral blood vessels, with a decided and progressive lowering of any existing abnormally high blood pressure.

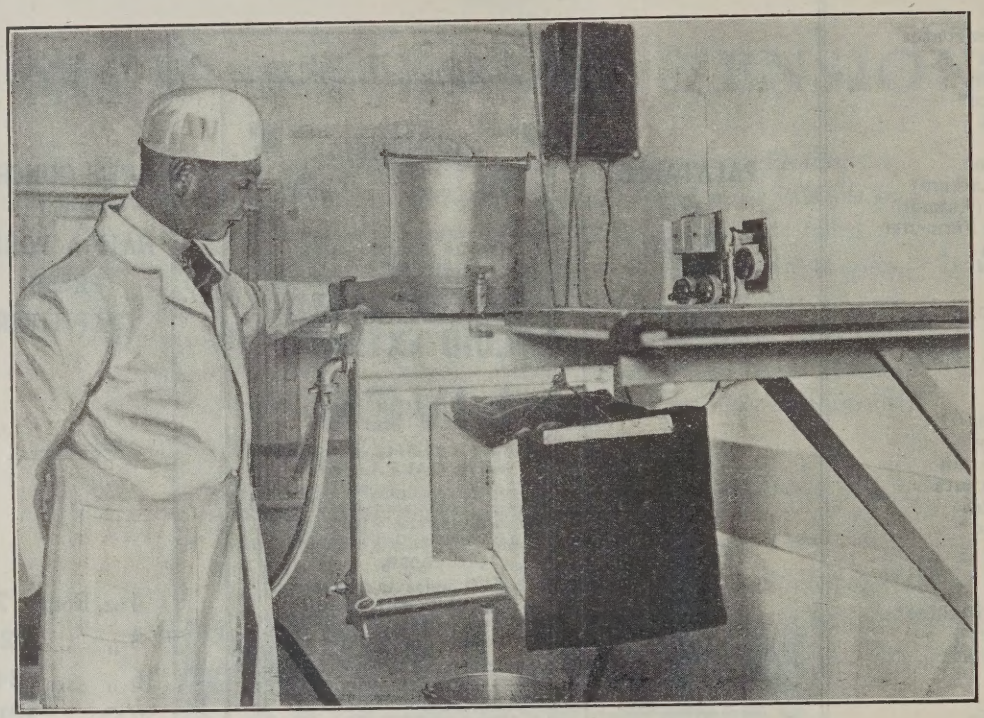
MICKLEFIELD IRRADIATED MILK



TREATING THE MILK.

By this Process—

(1) VITAMIN A AND NATURAL FLAVOUR ARE PRESERVED.
(2) VITAMIN D CONTENT IS INCREASED 1,800 PER CENT., OR TEN TIMES THAT OF ANY OTHER IRRADIATED MILK.

One pint equivalent in Vitamin D to 600 drops or 12 grammes of average Cod-Liver Oil.

A ten weeks' test recently conducted at the Infants' School, Rickmansworth, under the supervision of the Medical Officer of Health, gave the following results:—

(1) 18 children (controls) had their usual ordinary milk.
(2) 29 ,, 1/3-pint of Grade A (T.T.) milk five days a week.

The Answer to the "first Question"

INVARIABLY before prescribing for any ailment, the first question the physician asks the patient concerns the function of the bowels.

He then naturally asks himself what corrective, if any, to prescribe to suit the condition, without interfering with the treatment.

Agarol provides a safe answer to this.

Agarol Brand Compound the original mineral oil and agar-agar emulsion with phenolphthalein, is free from any artificial flavouring, sugar, alkali or alcohol. It is safe in diabetes, in gastric diseases, for children as well as adults. No excess of mineral oil to interfere with digestion or to cause leakage.

In addition, *gentle stimulation* of peristalsis, makes the result certain and the re-establishment of regular habits possible.

One tablespoonful at bedtime —is the adult dose.

Final decision on the true worth of Agarol Brand Compound rests with the physician. We will gladly send a liberal quantity with literature, for trial.

AGAROL BRAND COMPOUND *for Constipation*

FRANCIS NEWBERY & SONS, LTD., 31-33, Banner Street, London, E.C.1.

Prepared by WILLIAM R. WARNER & CO., INC., *Manufacturing Pharmacists Since 1856.*

"BYNOL"

'A perfect combination of Malt Extract with Cod-Liver Oil'—B.M.J.

'Bynol' contains 30% of the 'Allenburys' 'Perfected' Cod-Liver Oil

The 'Allenburys' 'Perfected' Cod-Liver Oil is examined biologically and certified as fully active with regard to Vitamins *A* and *D*.

The 'Allenburys' Malt Extract renders 'Bynol' a rich, easily digestible and palatable product.

Issued in wide-mouthed jars at 2/-, 3/6 and 6/6

Descriptive literature and a clinical sample will be sent post free on application.

CANADA—Lindsay, Ont. UNITED STATES—41 Maiden Lane, New York City.

Viosterol "A. & H."

Irradiated Ergosterol *(Vitamin D)* in Oil

Biologically Standardised

Viosterol "A. & H." is standardised to contain 10,000 units of Vitamin D in each c.c., i.e., it possesses 100 times the Vitamin D activity of good Cod-Liver Oil.

Viosterol "A. & H." is the specific treatment for rickets, tetany and other disturbances of the calcium-phosphorus metabolism.

Special advantages of Viosterol are the small dosage required, its prompt effect, palatability and absence of digestive disturbances.

Viosterol "A. & H." is issued in special rod-stoppered bottles containing 5 c.c. and 50 c.c.

Special literature on request.

INSTRUMENTS REPRODUCED FROM A MANUSCRIPT WORK OF ALBUCASIS, THE GREATEST ARABIAN SURGEON.—Oriental repugnance to opening the body and drawing blood prevented the Arabs from contributing greatly to the progress of surgery. They used cauteries generally in place of the knife in cancer and other growths, in gangrene, for the opening of hepatic abscess, and in carious inflammation of the hip joint. They had for this purpose an extraordinary number of instruments. Albucasis, however, made a valiant effort to revive the practice of surgery, convinced that in this direction lay the chief possibility of new progress in medicine. In the great surgical treatise, from which the accompanying figures are drawn, and which was for a large part of the Middle Ages the leading text-book on the subject, he thus laments the neglect of surgery: "The operative art has disappeared from among us almost without leaving any trace behind. Only in the writings of the ancients do we find some references to it, but these, by bad translations, by errors and alterations, have become nearly unintelligible and useless." The instruments here figured are a pair of concave scissors for the removal of tonsils, and an obstetrical appliance.

HOLLOW NEEDLE USED FOR THE REMOVAL OF CATARACT BY SUCTION

The Arabians were earnest workers in ophthalmology. They have left careful descriptions of their operations and illustrations of at least thirty-six oculist's instruments. Cataract was generally removed by depression of the lens into the vitreous. Cure by suction is described by Isa ben Ali in the work from which the accompanying illustration is reproduced. Of him an ancient Arabian historian records: "Ali ben Isa, or Isa ben Ali, a consummate oculist, composed a book entitled *Tedkirat el Kahhâlin'* (The Oculist's Memorial), a celebrated book, indispensable to every oculist and universally accepted to the exclusion of all others. He died in the four-hundredth year of the Hegira." Cure by suction had already been mentioned by Rhazes and by Albucasis, who had noticed the practice in Iraq. An eleventh century Arabian oculist, Omar ben Ali, seems to have employed this method. At the point of the instrument here figured is the direction: "This part is introduced into the eye"; and at the open end: "Through this part the cataract passes out."

STANDARD DILUTIONS FOR THE MEDICAL USE OF

"SANITAS" FLUID

For the Mouth, Nose and Throat, or cases of Catarrh, Coryza, Hay Fever, Sore or Septic Throat, Tonsillitis, Bronchitis, Diphtheria—Use "Sanitas" Fluid with two parts of warm water by spray, gargle, or insufflation.

For Cleaning Cuts, Ulcers, Abscesses, Sinuses, and for Deodorising Foul Discharges whether malignant or otherwise—Use "Sanitas" Fluid with an equal quantity of warm water.

As a Vaginal Douche and for Bladder Irrigation—Use one part "Sanitas" Fluid to three parts of warm water.

For Internal Use—"Sanitas" Fluid can be given as an intestinal antiseptic. *Dose:* One dram diluted with an equal quantity of warm water. In this connection it is incompatible with any drug liable to oxidation.

For Eczema, Seborrhœa, and Hæmorrhoids—Use one part "Sanitas" Fluid to three parts of warm water.

For Halitosis, Pyorrhœa, the care of Teeth (especially cavities after extraction)—Use one part "Sanitas" Fluid to three parts of warm water.

To renew devitalized atmospheres—Spray and sprinkle "Sanitas" Fluid undiluted.

N.B.—The essential ingredients of "SANITAS" Fluid are the products of the oxidation of certain Terpenes: they include Thymol and Peroxide of Hydrogen, of from 2 to 3 volumes in strength. "Sanitas" Fluid may therefore be used in place of the latter by reason of its greater antiseptic character.

STANIFORM

TRADE BRAND MARK

Methyl Stannic Iodide

OINTMENT
Immediately stops the pain in all cases of burns, scalds, &c.

DUSTING POWDER
For application where a greasy substance is counter-indicated.

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis.

LOTION
A panacea for Mosquito and other insect bites. Most effective for all purposes where Tr. Iodine is employed. Does not stain the skin and there is no sting.

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use.

Supplies may be obtained through the wholesale Druggists, Druggists' Sundriesmen, or Dental Supply Companies.

What the Profession says

The following are some recent unsolicited testimonials reported to the Manufacturers by Medical men:

"I have treated with Staniform a very bad scald of chest in a child, who had boiling water spilt over her. IT HEALED COMPLETELY IN FOURTEEN DAYS WITHOUT A SCAR."

"I have tried Staniform in the Out-Patients' Department, and both Nursing Staff and myself have been amazed at results obtained. Long-standing, non-healing skin wounds were cured after few applications."

"This is to certify that 'Staniform' has been used with great success in the Emma-Kliniek (Utrecht, Holland) in cases of Bed-sores, in Burns of heat, and X Ray burns."

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Ailments.

STANIFORM is used in leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties. Combining the well-known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing.

Vice-Chairman of Council.....Sir JOHN F. H. BROADBENT, BART., M.D.
Head Master of the School.....ARNOLD C. POWELL, Esq., M.A.

EPSOM COLLEGE.

EPSOM COLLEGE has an exceptionally fine position, with a dry, bracing climate, on the slope of Epsom Downs. The buildings include the War Memorial Chapel; large science buildings, with lecture theatre and several laboratories for physics, chemistry and biology; the Holman art room and the Propert library; a covered swimming bath, heated throughout the year; a gymnasium, a rifle range, a drill hall and armoury; a separate sanatorium (60 beds) with X-ray department and isolation annexe. There are also a museum, a carpenter's work shop, music rooms, fives courts, a pavilion and a laundry. Large central heating and hot water systems have recently been installed. There are over 30 acres of playing fields and 7 acres of vegetables.

For boys who have matriculated at the University of London, and who desire to enter the Medical Profession, the First Medical Examination of that University is conducted at Epsom College, and they are spared the expense of going to London for the purpose.

The General Council of Medical Education and Registration of the United Kingdom has included Epsom College in the list of Recognised Institutions approved of by that Council as places at which medical study may be commenced; and the College has been recognised as a School of Science by the Royal Colleges of Physicians and of Surgeons for the purpose of their Conjoint Diplomas.

Boys are also prepared for the Army, Navy, Air Force, Civil Service, the Universities and for Mercantile careers.

Ten Medical Scholarships, differing in value, and one Dental Scholarship are awarded annually at the Hospital Schools in London, and 32 leaving Scholarships, ranging in value from £15 to £105, are awarded under varying conditions, some of them annually, but most of them tenable for several years. Besides these, there are one "Dr. Robert Thomson and Phyllis Broughton" open Entrance Scholarship of £120 a year; one "Domett Stone" open Entrance Scholarship of £50 a year; and four "Salomons" Entrance Scholarships of £50 a year each. "Hugh Vardon" Scholarships of £24, and Junior open Scholarships of £60 are awarded annually.

ANNUAL FEES.—Sons of Medical Men, £135. Those who are not the sons of Medical Men, £155. Day Scholars, £57. These fees cover all the "extras" which used to be charged for separately under the heading "consolidated charges."

NEW SANATORIUM.

Since the publication of the plans of the New Sanatorium in *The Lancet* and *British Medical Journal* in December, 1927, the Council, with the help of friendly criticism from various Medical friends, has reconsidered both the plans and the site. A retired but convenient site, which stands back a quarter of a mile from the main road, away from the noise of traffic, has been selected.

The revised plans, prepared by the Architects, Messrs. William A. Pite, Son and Fairweather, show a three-storey building instead of the former two-storey building. The ground and first floors accommodate patients, while the second floor is occupied by rooms for the nursing and domestic staff.

The Main entrance faces North and all wards face South, the long axis of the building being East and West.

This new plan has made it possible considerably to increase the floor space per bed in the wards, and also to add to the number of Bath rooms and Sanitary Annexes. The positions of the Minor Surgery Operating Room and the X-ray Room have been reversed, the former is now placed next to the Casualty Room in the Out-patient Wing, and the latter near the Entrance Hall.

In October last the Council decided that it was imperative to commence building at once, and tenders were called for. That of Mr. E. H. Smith, of Croydon, for £26,245 was accepted, and work was started on October 16th. By the terms of the contract the building is to be completed in June, 1931, which will allow time for the conversion of the Old Sanatorium to its new use as a House for 50 boys in September, 1931.

A sum of over £8,400 has been received towards the cost of the building, and the Council will welcome further donations from those who feel that a College so closely connected with the Medical profession should possess a Sanatorium worthy to be a model for all other Public Schools.

A donor of £10,000 may give his own name, or the name of any person whom he desires to commemorate, to the Main Sanatorium; a donor of £5,000 may do likewise to the Isolation Wing; while a large ward may be named for £3,000, or a small ward for £1,000, and a single bed for £100.

ROYAL MEDICAL FOUNDATION.

FIFTY FOUNDATION SCHOLARS receive an education of the highest class in Epsom College, and are boarded, clothed, and maintained at the expense of the College. They must be elected, after approval by the Council, from among the sons of necessitous Medical Men who have been Registered Medical Practitioners for five years.

FIFTY ORDINARY PENSIONERS, who must be legally qualified Medical Men registered for five years, or the Widows of such, receive an annual pension. They must be not less than 60 years of age at the time of their application for admission as candidates.

The Ordinary Pensioners and the Foundation Scholars are elected by the Governors, voting by ballot, and having votes in proportion to the amount of their contributions. There is one election in the year, namely, in June. The Ordinary Pupils, the majority of whom are sons of Medical Men, pay fees which cover the entire cost of their board and education.

A sum of close upon £9,000 is required annually to maintain 50 Foundation Scholars and 50 Pensioners, yet this leaves much destitution in the profession untouched. The Council earnestly plead for more and larger subscriptions, so that they may extend the work to the relief of this distress. The profession and the public are therefore asked to make the Royal Medical Foundation attached to the College a refuge in time of trouble for all those members of a great profession and their children who fall on evil days.

Donors of 10 guineas, and collectors of 20 guineas, are Life Governors of the College; Subscribers of one guinea annually are Governors during the continuance of their subscriptions.

J. BERNARD LAMB, Secretary.

Office: 49, Bedford-square, W.C. 1.

The North-East London Post-Graduate COLLEGE.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

PRESIDENT: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.
MEDICAL SUPERINTENDENT: DANIEL F. RAMBAUT, M.A., M.D.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, bio-chemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital, in detached grounds with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian Baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, &c. There is an operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for bio-chemical, bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit and vegetables are supplied to the Hospital from the farm, gardens and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard court), croquet grounds, golf courses and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts such as carpentry, &c.

For terms and further particulars apply to the Medical Superintendent (TELEPHONE: No. 56 Northampton), who can be seen in London by appointment.

BETHLEM ROYAL HOSPITAL

FOR NERVOUS AND MENTAL DISORDERS,

Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

Reg. Tel. Address: BETHLEM, BECKENHAM.
Station: EDEN PARK (Southern Railway).

President: LORD WAKEFIELD OF HYTHE, C.B.E., LL.D. *Treasurer:* Sir LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Superintendent: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure and farm grounds, and is ready to receive patients. Application can now be considered on behalf of patients of the educated classes in a presumably curable condition.

With a view to early treatment, voluntary or uncertified patients are admitted.

Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates and in certain cases will be prepared to admit patients free of charge.

Every facility for specialised investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X-Ray and Dental Departments, and the Bio-Chemical, Pathological and Psychological Laboratories.

Furthermore provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.

In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.

The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.

For forms and further particulars apply to the Physician-Superintendent at the Hospital.

CAMBERWELL HOUSE,

Telegrams: "PSYCHOLIA, LONDON." **33, PECKHAM RD., LONDON, S.E. 5.** Telephone: Rodney 4731, 4732.

The Hospital for Sick Children,

Great Ormond-street, London, W.C.1.

A Part-time JUNIOR CASUALTY OFFICER is required on the 9th January, 1931, to assist in the Casualty Department from 10 A.M. to 3 P.M. (Saturdays 10 A.M. to 1 P.M.), under the direction of the Casualty Officer.

The work of this Officer includes a large number of tonsillectomies and other minor operations.

Candidates must be registered Medical Practitioners, and have held a responsible Hospital appointment.

Gentlemen are invited to send in their applications, addressed to the Secretary, before 12 o'clock on Monday, 5th January, 1931, accompanied by copies of not more than three testimonials written specially for the purpose.

The appointment is made for six months, and is non-resident.

Salary at the rate of £150 per annum, with luncheon.

All candidates must be in attendance to appear before the Joint Committee, if required, at their meeting on Wednesday, 7th January, 1931, at 4.45 P.M. precisely.

Forms of application and copies of the rules may be obtained from the Secretary, at the Hospital.

By order of the Board of Management.
December, 1930. JAMES MCKAY, Secretary.

County Council of Middlesex.

The County Council invites applications from duly qualified medical practitioners for the undermentioned appointments:—

DISTRICT MEDICAL OFFICER, Tottenham (High Cross).

Salary £180 per annum. The Officer appointed will be required to carry out his duties in accordance with the Public Assistance Order, 1930, of the Minister of Health, to reside in the district, and to name to the Council some duly qualified medical practitioner who will, in the case of his absence or other hindrance to his personal attendance, act in his place.

PUBLIC VACCINATOR, Tottenham (High Cross).

The person appointed will be required to produce to the Council a certificate of proficiency in vaccination, unless such certificate was required as a condition of obtaining any diploma, licence or degree which he possesses.

He will be required also to enter into a contract with the Council in accordance with the Vaccination Order, 1930, of the Minister of Health. The contract will provide for the payment of the minimum fees laid down in the Order.

Applications, stating (1) name, (2) age, (3) qualifications and experience, accompanied by copies of not more than three recent testimonials, must be received by the undersigned not later than 10th January, 1931.

No special application forms are provided. Envelopes must be endorsed "District Medical Officer" or "Public Vaccinator," as the case may be.

Canvassing, directly or indirectly, will be a disqualification.

ERNEST S. W. HART, Clerk of the County Council.

Guildhall, Westminster, S.W.1., 18th December, 1930.

Rotherham Hospital.—Wanted,

HOUSE PHYSICIAN (Male), qualified. Salary £180 p.a., with board, residence, and laundry; to have charge of Out-patients, administer anæsthetics, and assist Honorary Physician.

Applications, with copies of recent testimonials, to be sent to the Secretary, G. W. ROBERTS, 8, Moorgate-street, Rotherham.

INDIAN MEDICAL SERVICE

RECRUITMENT OF EUROPEAN OFFICERS

Applications are invited from Medical Men for permanent commissions in H.M.'s Indian Medical Service. The Terms offered include a gratuity of £1,000 on retirement after six years' service or £2,500 after 12 years' service, together with free return passages for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after one year's Indian Service to have his name registered for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of Civil Officials and for general medical administrative purposes; to specialist (e.g., Public Health and Bacteriological) services; to research posts; and to professorships at the Medical Schools.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:—

Rank.	Service in Rank.	Basic Pay.	Overseas Pay.	Year of Total Service.
1	2	3	4	5
		Rs.		
Lieut...	—	500	Rs.150	1st
			150	2nd
			150	3rd
Capt...	(i) During first 3 years' service as Captain ..	650	150	4th
			£15	5th
			15	6th
	(ii) With more than 3 and less than 6 years' service as Captain	750	25	7th
			25	8th
			25	9th
	(iii) With more than 6 years' service as Captain	850	25	10th
			25	11th
			30	12th
Major ..	(i) During first 3 years' service as Major ..	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major..	1250		
Lt.-Col.	(i) Until completion of 23 years' total service ..	1500	30	13th and over.
	(ii) During 24th and 25th years' service	1600		
	(iii) After completion of 25 years' total service ..	1700		
	(iv) When selected for increased pay	1850		

Extras.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

ANTEDATES IN COMMISSION.

Any service rendered by an officer during the War as a medical or combatant officer or in a position usually filled by an officer may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the War may be counted as service for retirement and retired pay only.

Candidates possessing certain higher medical qualifications may be granted an antedate of one year in their commissions. Past service in certain hospital appointments may also render candidates eligible for an antedate of one year. Persons holding or about to hold resident posts at recognised hospitals may be seconded in those posts for a period not exceeding one year. The maximum period of antedate, secondment, or antedate and secondment combined, admissible under this paragraph, is limited to one year.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

LEAVE.

Leave can be taken at reasonable intervals, and adequate rates of leave pay are provided. Extra leave (known as study leave), which may not exceed 12 months in all during an officer's service, may be granted to officers desirous of pursuing special courses of study of a post-graduate nature. During such leave, study allowance, at present fixed at the rate of 12*s.* a day in the United Kingdom, £1 a day on the Continent of Europe, and £1 10*s.* a day in the United States of America, is granted to an officer in addition to ordinary rates of leave pay.

PENSIONS.

The rates of pension are as follows:—

	Per annum.
After 17 years' service for pension ..	.. £400
,, 18 ,, ,, ..	.. 430
,, 19 ,, ,, ..	.. 460
,, 20 ,, ,, ..	.. 500
,, 21 ,, ,, ..	.. 540
,, 22 ,, ,, ..	.. 580
,, 23 ,, ,, ..	.. 620
,, 24 ,, ,, ..	.. 660
,, 25 ,, ,, ..	.. 700
,, 26 ,, ,, ..	.. 750
,, 27 ,, ,, ..	.. 800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919, to an extent not exceeding 20 per cent. in all, the revision being undertaken triennally. With effect from July 1st, 1930, a reduction of 5¼ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the UNDER-SECRETARY OF STATE FOR INDIA, MILITARY DEPARTMENT, INDIA OFFICE, LONDON, S.W.1.

The Selection Committee will meet at the India Office early in January next, and the selected candidates will be required to join a course of instruction commencing early in February, 1931, prior to sailing for India in the Autumn of 1931.

Applications should be submitted as soon as possible.

Chesterfield and North Derbyshire ROYAL HOSPITAL.

PRACTICES AND PARTNERSHIPS FOR SALE.

1. WITHIN 100 MILES OF LONDON (NORTH).—PARTNERSHIP.—The two-sevenths share (with option to third and eventually half), producing about £1000 p.a., is offered in very old-estab. Practice averaging about £3500 p.a., including panel of 2500. Situated in pleasant town with pop. of 2000. Ingoing partner should be unmarried (about 25 to 30) until suitable house available. Premium 2 years' purchase. Short preliminary assistantship.
2. WEST MIDLANDS.—Within seven miles of County Town —Old-estab. unopposed country PRACTICE, in pretty district, averaging nearly £2400 p.a., including appt. over £100, and panel upwards of 1000. Railway station. Very nice house and garden, with tennis court. Price (Copyhold) £1000, £500 on mortgage. Premium 1½ years' purchase, payable as arranged. Sport of all kinds, and exceptionally good educational facilities.
3. WITHIN FIFTY MILES OF LONDON.—Old-estab. chiefly better-class PRACTICE situated in very good residential district. Gross cash receipts for past 12 months approximately £2000, with panel producing about £340 p.a. Fees 5s. to 21s. Exceptionally nice house, in own grounds, with 3 reception, 5 bedrooms, &c. Freehold for sale. Premium £3000.
4. PARTNERSHIP. — SURREY. — Attractive residential district within 40 miles.—A one-half share, with ultimate succession, is offered in a good mixed Practice, averaging about £1500 p.a., but capable of large increase. Panel of over 1000. Fees 3s. 6d. to 21s. Suitable house with 3 reception and 3 bedrooms, &c. Good garden. Price for freehold £1500, £1000 on mortgage. Premium 1½ years' purchase.
5. NEAR FOREST OF DEAN.—Old-estab. country PRACTICE, in picturesque surroundings, averaging about £1250 p.a. Panel of 1100. Visits from 3s. 6d. Suitable house with 3 reception, 6 bedrooms, &c. Garden. Price for freehold £1500, of which £1000 on mortgage. Premium £350 cash, and £1500 by instalments over five years.
6. HOME COUNTIES.—County Town.—Rapidly increasing PRACTICE, at present producing about £450 p.a., but offering large scope. Panel of 265. Fees from 2s. 6d. Good house with 4 reception, 5 bedrooms, &c. For sale or on rental. Good sport and excellent schools. Premium 1½ years' purchase.
7. SOUTH COAST TOWN.—Rapidly increasing PRACTICE producing for last 12 months over £400. No panel. Visits 5s. upwards. Suitable house with 2 reception. 3 bedrooms, &c. Rent on lease £130. Premium £600.
8. MIDLANDS. — County Town. — Old-estab. better-class PRACTICE, averaging £793 p.a., and offering good scope. Panel of 500. Fees 5s. upwards. Well-situated house with good garden, with 3 reception, 4 bedrooms, &c. Separate surgery. Rent on lease £111 p.a. Premium 1¼ years' purchase.
9. GLOS.—Unopposed very old-estab. PRACTICE, in beautiful agricultural district, worth over £600 p.a., including appt. of £90 and panel of 480. Very nice house (5 bedrooms, &c.), water laid on, electric light, 1 acre of ground. Price freehold £2000, or would be rented. Another smaller house is also available. Premium £750. Good social amenities, and scope for increase.
10. SOUTH OF ENGLAND.—Coast Town.—PARTNERSHIP. —A share guaranteed to produce £600 per annum is offered to a suitable man, keen on surgery, and pref. holding the F.R.C.S. Rapidly increasing Practice, having large scope. Panel of over 1400. Fees from 3s. 6d. Suitable house can be secured. Premium 2 years' purchase.
11. CHESHIRE.—Coast Town, within reach of Liverpool.— Well-estab. PRACTICE, averaging over £1200 p.a., including panel of 780. Fees from 3s. 6d. Mid. 2 to 5 gns. Double-fronted house, with 3 reception, 4 bedrooms, &c. Price for freehold £1400, £800 on mortgage. Premium 1½ years' purchase, £1100 down.
12. LONDON, SOUTH-WEST.—Old-estab. non-panel PRACTICE, having good Ophthalmic connection, and also scope for Ear, Nose, and Throat work. Gross cash receipts for past 12 months over £1400. Fees from 5s. Practically no Midwifery, but scope if desired. Good corner house in excellent condition, with 4 reception, 5 bedrooms, &c. Price for long lease £1500. Premium 1½ years' purchase.
13. SOUTH COAST.—Favourite Health Resort.—Well-estab. mixed-class PRACTICE, offering good scope. Average gross cash receipts over £700 p.a., including panel of 720. Very good house, with 2 reception, 5 bedrooms, &c. Nice garden. To be sold, or might be let for a time. Premium 1½ years' purchase.
14. YORKSHIRE.—Good Town.—PARTNERSHIP.—A one-half share guaranteed to produce £2000 p.a. in first year is offered in a good middle-class Practice. Income for the past twelve months approximately £4000. Small selected panel of 430. One appointment worth nearly £650 p.a. Fees 3s. 6d. upwards. Opposition not strong. Suitable house can be bought or leased. Very good educational and sporting facilities. Premium 2 years' purchase.
15. YORKS.—Large Town.—Old-estab. middle- and working-class PRACTICE averaging £1778 p.a. Panel of 791. Fees 3s. 6d. to 21s. Mid. 2 to 10 gns. About 12 cases yearly. Suitable house with 2 reception, 4 bedrooms &c. Separate entrance to professional rooms. Good schools and sporting facilities. Premium 1½ years' purchase.
16. HOME COUNTIES.—PARTNERSHIP.—A third share, producing about £1000 p.a. is offered in a well-estab., good mixed-class Practice situated in very attractive district within 20 miles of London. Fees 3s. 6d. to 2 gns. Suitable house available. Prem. 2 years' purchase.
17. LANCS.—PARTNERSHIP.—A one-fourth share to commence (with increase up to one-half later) is offered in a very old-established, good, middle-class Practice, producing for the last twelve months over £4700 p.a. Panel of 2730. Appts. worth nearly £200 p.a. Visits 2s. 6d. to 12s. 6d. Not much midwifery from 2 to 3 gns. Suitable house obtainable, but, if single, purchaser can reside with Vendor, who is a bachelor. Premium 2 years' purchase.
18. CAMBS.—PARTNERSHIP.—A one-half share is offered in a sound mixed-class Practice, producing last year nearly £2000. Panel of 765. Situated in pleasant agricultural district, with good sporting facilities. Fees 5s. to 21s. Suitable house can be rented at £75 p.a. Premium 2 years' purchase.
19. YORKS.—In small pleasant market town, amidst pretty and prosperous surrounding country, very old-estab. mixed-class PRACTICE, averaging nearly £1250 p.a., including panel and appts. worth over £450. Visits 3s. 6d. to 25s. Opposition weak. Good house, with ample accommodation and every convenience. Garden. Garage. Price £1300; £1000 on mortgage, or would be let at £80 p.a. Premium £1450. Educational and social amenities.
20. SOUTH-WESTERN COUNTY.—Near the Sea. Old-estab., easily worked country PRACTICE, in beautiful district, within reach of market town and averaging £1100 p.a., including appts. and panel producing £450. Exceptionally attractive modernised house in over 3 acres of ground, with ample accommodation; productive fruit and vegetable garden, with tennis lawn, &c. Water laid on and electric light available shortly. Price freehold £3000, part on mortgage. Premium £1650. Sport of all kinds and schools within reach.
21. LONDON, S.E.—Outlying Residential Suburb.—Very old estab. PRACTICE (hitherto carried on by two men in partnership) is for disposal, or half share would be sold with Succession to the whole in 12 months' time. Receipts average about £3000 p.a., including appts. worth over £330 and panel over 1500. Two houses available. Prem. 1½ years' purchase. Eminently suitable for two friends.

ASSISTANTS REQUIRED.—(1) Home Counties. Outdoor. £450. (2) Suffolk. Indoor or Outdoor. £300 or £400 p.a. (3) Wilts. Outdoor. £450 p.a. (4) Lincs. Country Practice: £300. Indoor. (5) London, N. Outdoor. Married, £400 p.a., with free unfurnished house.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)

(Founded 1880)

Tele. Address: Triform, Wesdo—London. **12, Stratford Place, Oxford Street, W.1.** Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic, and Accountancy business, and the British Medical Association has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

MEMBERS OF THE BRITISH MEDICAL ASSOCIATION MAY TAKE ADVANTAGE OF A REDUCED SCALE OF CHARGES APPLICABLE TO THEM.

For the sake of reference the business undertaken by the BRITISH MEDICAL BUREAU is divided under the following heads :—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the BRITISH MEDICAL BUREAU. Vendors may depend upon receiving introductions only to eligible and bona fide purchasers. All information is treated in strictest confidence.

Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the BRITISH MEDICAL BUREAU to ensure that only the most TRUSTWORTHY AND RELIABLE Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the BRITISH MEDICAL BUREAU. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The BRITISH MEDICAL BUREAU has its own staff of fully qualified Accountants wholly engaged on Medical work, i.e., Investigation of Practices for purchasers, Income Tax, Auditing books and accounts, etc.

SCHOLASTIC DEPARTMENT.

Medical Men will find this Department of the BRITISH MEDICAL BUREAU of great assistance in the selection of Educational Establishments, Private Tutors, Governesses, etc. Prospectuses and advice gratis.

All correspondence and applications should be addressed to **A. V. STOREY, General Manager.**

Metropolitan Borough of Finsbury.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH.

The Finsbury Borough Council invites applications from registered medical practitioners for the appointment of an Assistant Medical Officer of Health. The appointment will be a full-time one. The duties will be allocated as to two-thirds of the time to tuberculosis, while the remaining one-third will be available for general public health work.

The salary will be at the rate of £750 per annum.

The appointment will commence at an early date and will be subject to a medical examination and to the provisions of the Council's Superannuation Scheme.

Applications, endorsed "Assistant Medical Officer of Health," and accompanied by copies of not more than three recent testimonials, must be received by the undersigned not later than the first post on January 10th, 1931.

There are special forms of application which may be obtained from the Medical Officer of Health at the address given below on application either by post or personally.

Canvassing is prohibited and will disqualify.

(Signed) HUGH GREEN, Town Clerk.
Finsbury Town Hall, Rosebery Avenue, E.C. 1.

The Royal Sea Bathing Hospital
FOR SURGICAL TUBERCULOSIS, Margate.

HOUSE SURGEON REQUIRED.

A Male House Surgeon is required to take up duty in January, 1931. The salary is at the rate of £200 per annum, with board, residence, attendance, and laundry.

Candidates for the post must be legally qualified and registered. The appointment is for six months.

There are 308 beds for adults and children, which afford special opportunities for the study of surgical tuberculosis.

Applications, stating age and previous appointments, with copies of three recent testimonials, should be sent to the Secretary, R.S.B.H. Offices, 15, York Buildings, Adelphi, London, W.C. 2.

Demy 8vo. Cloth. 388 pp. Price 10/6 net (postage 9d. extra).

PRESS OPINIONS

"Each of the forty-five sections included in the book is contributed by an experienced worker, and the discussion is by no means a severely technical or limited one. On the contrary, each topic means a short and readable chapter in which an attempt is made to show where clinical findings can be enlarged by particular tests and in what measure the results of the tests help the practical situation. . . . Two small practical points deserve a word of recognition—namely, the interleaved blank pages for personal notes, and the well-written summaries that precede the several sections; these summaries are indeed triumphs in the art of combining brevity with lucidity, and they serve well the purpose for which they have been constructed."—*British Medical Journal.*

"Everything is done for the busy G.P."—*Journal of Medical Association of South Africa.*

"Each writer not only indicates when a particular test is necessary, but also shows how the report of the test is interpreted by the practitioner in every case. . . . These volumes are sure to prove helpful to the medical man who wishes to keep in touch with modern methods of diagnosis and treatment."—*Medical World.*

"This series will form a useful sequel to the Volumes on Treatment recently issued."—*The Prescriber.*

"The writers have been chosen with successful discretion, and this volume fully deserves the respect and demand that will ensure its rapidly becoming out of print."—*The Practitioner.*

To THE MANAGER, THE LANCET LTD.,
7, ADAM STREET, ADELPHI, LONDON, W.C.2.

Please send me ..... cop ..... of "THE CLINICAL INTERPRETATION OF AIDS TO DIAGNOSIS," Vol. 1, price 10s. 6d. net (postage: inland 6d., abroad 9d., extra), for which I enclose remittance.

SELECTED ENGLISH WHEAT
Dextrinised and Pancreatised

PREDIGESTED MILK
(25% Protein Conversion)

PREDIGESTED WHEAT
(25% Starch Conversion).

Powdered by the
COW & GATE
Improved
Roller Process

Peptalac REGD.

THE NEW INSTANT PREDIGESTED FOOD

Predigestion of starch *and* milk is guaranteed and is effected under the most exact scientific conditions in our laboratories before powdering. This means that when required for use it can be immediately and simply prepared by the *mere* addition of hot water. The C. & G. Improved Roller Process is used ensuring retention of the full mineral and vitamin content with freedom from pathogenic organisms.

PEPTALAC is indicated in all those cases where the powers of the digestive tract are insufficient to deal with that amount of food necessary for maintaining health—for nursing mothers with weak digestions, in ante- and post-operative surgical cases, in achlorhydria, peptic ulceration, cancer of the alimentary tract, in all forms of convalescence and in old age.

Antiphlogistine

Acute Sinusitis

may be due to:

1. Vacuum—inflammatory closure of the sinus, and subsequent absorption of air;
2. Pressure of accumulated exudate;
3. Toxic influence upon nerve terminals of pus and other inflammatory products.

SUCCESS in the treatment of these cases depends upon the establishment of free drainage and ventilation.

Antiphlogistine applied over the affected region will help to:

1st—Relieve the pain;

2nd—Dissipate the congestion;

3rd—Establish drainage of the diseased sinus.

By virtue of its prolonged hyperaemic, osmotic and antiseptic powers, Antiphlogistine activates lymph circulation and relieves the swelling and congestion of the mucosa.
